358

359 **Stroke has multiple etiologies but the underlying genes and pathways are largely**  
360 **unknown. We conducted a multi-ancestry genome-wide association meta-analysis in**  
361 **521,612 individuals (67,162 cases and 454,450 controls) and discovered 22 novel stroke**  
362 **risk loci bringing the total to 32. We further found shared genetic variation with related**  
363 **vascular traits including blood pressure, cardiac traits, and venous thromboembolism at**  
364 **individual loci (N=18), and using genetic risk scores and LD score regression. Several**  
365 **loci exhibited distinct association and pleiotropy patterns for etiological stroke subtypes.**  
366 **Eleven novel loci point to mechanisms not previously implicated in stroke**  
367 **pathophysiology, with prioritization of risk variants and genes accomplished through**  
368 **bioinformatics analyses using extensive functional datasets. Stroke risk loci were**  
369 **significantly enriched in drug targets for antithrombotic therapy.**  
370

371 Stroke is the second leading cause of death and disability-adjusted life-years worldwide.<sup>1,2</sup>  
372 Characterized by a neurological deficit of sudden onset, stroke is mostly caused by brain  
373 infarction (ischemic stroke) and, less often, intracerebral hemorrhage (ICH). Common  
374 etiological subtypes of ischemic stroke include large artery atherosclerotic stroke (LAS),  
375 cardioembolic stroke (CES), and stroke caused by small vessel disease (small vessel stroke,  
376 SVS), the latter being also the leading cause of ICH. Previous genome-wide association  
377 studies (GWAS) in predominantly European ancestry groups have identified 10 loci robustly  
378 associated with stroke.<sup>3-12</sup> In most instances, the association with stroke could be attributed to  
379 individual subtypes of ischemic stroke, such as LAS<sup>5,8,9</sup>, CES<sup>3,4</sup>, and SVS<sup>10,12</sup> or of ICH<sup>6</sup>  
380 although some loci were associated with two or more stroke subtypes<sup>7,9,11,13</sup> or with any  
381 stroke.<sup>10</sup> We hypothesized that combining a substantially enlarged sample size with a  
382 transethnic analytic approach would identify additional risk loci and improve fine mapping of  
383 causal variants. Hence, we combined all available stroke samples with published or  
384 unpublished GWAS data including samples of non-European ancestry that were  
385 underrepresented in previous GWAS. We further hypothesized that stroke shares genetic  
386 influences with vascular risk factors, intermediate phenotypes for stroke (e.g., carotid artery  
387 plaque, cPL), and related phenotypes (e.g., coronary artery disease, CAD) and that a  
388 systematic approach to identify genetic influences shared among these traits would provide  
389 insights into stroke pathophysiology.  
390

## 391 RESULTS

392

393 We tested ~8 million single nucleotide polymorphisms (SNPs) and InDels with minor allele  
394 frequency (MAF)  $\geq 0.01$  in up to 67,162 stroke cases and 454,450 controls for association  
395 with stroke. One analysis was of European participants only (40,585 cases; 406,111 controls)  
396 and a second involved participants of European, East-Asian (17,369; 28,195), African (5,541;  
397 15,154), South-Asian (2,437; 6,707), mixed Asian (365; 333), and Latin-American (865; 692)  
398 ancestry (**Fig. 1**). Participants were drawn from 29 studies with genome-wide genotypes  
399 imputed to 1000 Genomes phase 1v3 or similar<sup>14</sup> (The MEGASTROKE consortium,  
400 **Supplementary Note, Supplementary Tables 1-2**). Ancestry-specific meta-analyses were  
401 conducted followed by fixed-effects transethnic meta-analyses and MANTRA transethnic  
402 meta-analyses.<sup>15</sup> Analyses were performed for any stroke, comprising ischemic stroke, ICH,  
403 and stroke of unknown or undetermined type (any stroke, AS, N=67,162), any ischemic  
404 stroke regardless of subtype (AIS, N=60,341) and ischemic stroke subtypes (LAS, N=6,688;  
405 CES, N=9,006; SVS, N=11,710).

406

407

### 408 *Genome-wide association results*

409

#### 410 **New genome-wide significant stroke loci**

411 We identified 32 genome-wide significant loci, 22 of which were novel (**Table 1, Fig. 2,**  
412 **Supplementary Tables 3-4, Supplementary Fig. 1-7**). Of the 22 novel loci, 18 were  
413 identified by transethnic meta-analyses (fixed effects p-value  $< 5.0 \times 10^{-8}$  or MANTRA  
414  $\log_{10}(\text{Bayes factor})[\text{BF}] > 6$ ) (**Fig. 2 and Supplementary Fig. 1-5**) and the remaining 4 were  
415 identified by the ancestry-specific meta-analysis in European samples (fixed effects p  $<$   
416  $5.0 \times 10^{-8}$ ) (**Fig. 2 and Supplementary Fig. 1-5**). Apart from 2 novel loci with a MAF between  
417 0.01 and 0.05 and large effect size estimates (odds ratios [ORs] of 2.33 and 1.95), the  
418 remaining 20 novel loci harbored common variants (MAF 0.16-0.48) with observed ORs  
419 between 1.05 and 1.20 (**Table 1**). Comparison of the 32 loci across Europeans and East-  
420 Asians, the two largest ethnic subgroups, demonstrated significant correlations of risk allele  
421 frequencies and ORs between populations (**Supplementary Fig. 8**), although 6 loci exhibited  
422 population-specific association (defined as p  $< 5.0 \times 10^{-8}$  in Europeans and p  $> 0.05$  in East-  
423 Asians or MAF in East-Asians  $< 0.01$ ) (**Supplementary Table 5**). Estimates for the  
424 phenotypic variance explained by the 32 lead variants ranged between 0.6% and 1.8%  
425 (**Supplementary Table 6**).

426 Gene-based tests using VEGAS2<sup>16</sup> (**Supplementary Fig. 9**) confirmed the loci identified by  
427 the GWAS analyses above, and yielded a novel significant (p  $< 2.02 \times 10^{-6}$ , Bonferroni  
428 corrected for the number of genes) association for the neighbouring genes *ICA1L* and *WDR12*  
429 with SVS (**Supplementary Table 7, Supplementary Fig. 9-10**). Prior studies have  
430 demonstrated that variants in this region are associated with white matter hyperintensity  
431 (WMH) burden<sup>17</sup> a brain magnetic resonance imaging marker of small vessel disease (SVD).  
432 Twenty-one additional loci met a less stringent threshold for suggestive evidence of  
433 association ( $\log_{10}[\text{BF}] > 5.0$  or p  $< 1.0 \times 10^{-6}$  in the transethnic fixed effects  
434 analysis) (**Supplementary Table 8**), among them three loci previously implicated in  
435 Mendelian stroke (*HTRA1*<sup>18,19</sup>, *COL4A1*<sup>20</sup>, and *COL4A2*<sup>21</sup>).

436

437

438

#### 439 **Associations with etiological stroke subtypes**

440 Eighteen loci (12 novel) reached genome-wide significance for AS, 20 (12 novel) for AIS  
441 (20), 6 (3 novel) for LAS, 4 (2 novel) for CES, and 2 (*ICA1L-WDR12* novel, discovered in

442 gene-based tests) for SVS (**Fig. 2, Table 1, Supplementary Fig. 1-5 & 10**). Several loci  
443 reaching genome-wide significance for one of the ischemic stroke subtypes were also  
444 genome-wide significant for AIS or AS, while none reached genome-wide significance for  
445 multiple ischemic stroke subtypes (**Fig. 2, Supplementary Table 9**). For some novel loci, the  
446 association was strictly confined to a single subtype ( $p > 0.5$  for other stroke subtypes):  
447 *EDNRA* and *LINC01492* showed association with LAS only, suggesting mechanisms limited  
448 to atherosclerosis; *NKX2-5* showed association with CES only, implying that the association  
449 may be primarily mediated by cardioembolism. We also found subtype-specificity for  
450 previously published loci (*TSPAN2* for LAS and *PITX2* for CES). We further investigated  
451 shared genetic influences of individual loci on different stroke subtypes using gwas-pw  
452 analyses<sup>22</sup>, which estimate the posterior probability that a specified genomic region influences  
453 two different traits. Applying a posterior probability cut-off of 90% for shared contribution at  
454 a given locus (model 3) we found shared genetic influence between LAS and SVS at *SH2B3*,  
455 and between LAS and CES at *ABO* (**Supplementary Table 10 and Supplementary Fig. 11**).  
456

### 457 **Conditional analysis to identify independent signals within loci**

458 When conditioning all SNPs in a  $\pm 0.5$  Mb window on the lead SNPs in the Europeans-only  
459 analysis, we found two additional independent genome-wide signals at the *PITX2* locus for  
460 CES, consistent with known multiple independent loci at *PITX2* for atrial fibrillation (AF),<sup>23</sup>  
461 suggesting that a similar genetic architecture at this locus influences both conditions  
462 (**Supplementary Fig. 12**). We further found suggestive independent signals at *MMP12*,  
463 *SH2B3*, and *HDAC9-TWIST1* that did not reach genome-wide significance (**Supplementary**  
464 **Table 11**).  
465

### 466 **Genetic overlap with related vascular traits**

#### 469 **Association of individual stroke risk variants with related vascular traits**

470 Several of our loci are in genomic vicinity of established risk loci for vascular risk factors  
471 (e.g., blood pressure, BP), and related vascular phenotypes affecting the heart (e.g., CAD),  
472 vasculature (e.g., carotid intima media thickness, cIMT), or brain (WMH). To systematically  
473 explore genetic overlap between stroke and these traits we surveyed published GWAS for BP,  
474 blood lipids, type 2 diabetes (T2D), cIMT, cPL, AF, venous thromboembolism (VTE), CAD,  
475 and WMH, assembled through the IGEN-BP<sup>24</sup>, ENGAGE<sup>25</sup>, DIAGRAM<sup>26</sup>, CHARGE<sup>27,28</sup>,  
476 AFGen<sup>29</sup>, INVENT<sup>30</sup>, and CARDIoGRAMplusC4D<sup>31</sup> consortia (**Supplementary Table 12**).  
477 When constructing sets of index SNPs of the non-stroke phenotypes (Bonferroni adjusted  $p <$   
478  $1.3 \times 10^{-4} = 0.05/32$  loci/12 related vascular traits) and SNPs in high LD ( $r^2 > 0.9$  in 1000G  
479 EUR) with those index variants, 17 of the 32 stroke lead variants showed overlap with these  
480 sets (**Supplementary Table 13, Fig. 3**). Fourteen loci reached genome-wide significance ( $p <$   
481  $5.0 \times 10^{-8}$ ) for association with one or more of the following phenotypes: BP (5 loci), CAD (5  
482 loci), AF (2 loci), VTE (2 loci), LDL-cholesterol (2 loci), cPL (1 locus), and WMH (1 locus).  
483 Among the 21 additional subthreshold loci for stroke (**Supplementary Table 8**) 6 loci have  
484 previously been associated with related vascular traits including AF (*PRRX*<sup>32</sup>, *CAVI*/<sup>32</sup>),  
485 VTE (*F11*<sup>30</sup>), CAD (*SWAP70*, *LPA*<sup>31</sup>), blood lipids (*LPA*<sup>31</sup>), and WMH (*ICAIL-WDR12*<sup>28</sup>).  
486

#### 487 **Association of genetic risk scores of related vascular traits**

488 Second, we generated weighted genetic risk scores (wGRS) for VTE, BP-related traits, blood  
489 lipids, T2D, and CAD using the lead SNPs from published GWAS and tested these wGRS for  
490 association with each stroke phenotype, implementing the inverse-variance weighting  
491 approach (**Methods, Supplementary Table 14**). We found significant associations ( $p <$   
492  $5.6 \times 10^{-3}$  correcting for 9 independent phenotypes, see Methods) with wGRS for all traits

493 examined, except for triglyceride and LDL-cholesterol levels, with clear differences between  
494 stroke subtypes (**Fig. 4**). The strongest association was between the wGRS for CAD and LAS  
495 consistent with shared pathophysiology through atherosclerosis. We further found  
496 associations of all stroke subtypes with wGRS for BP traits. The wGRS for VTE was  
497 significantly associated with both LAS and CES (all  $p < 1.0 \times 10^{-4}$ ) but not SVS. The wGRS  
498 for HDL-cholesterol showed a significant inverse association with SVS.

499 In the present setting the wGRS analysis was used primarily to explore the genetic overlap  
500 with related vascular traits, not as a tool for establishing causal inference. In sensitivity  
501 analyses we conducted an MR-Egger regression to explore whether any of the significant  
502 associations between vascular wGRS and stroke may be partly driven by directional  
503 pleiotropy. There was no indication of directional pleiotropy except for the association  
504 between the SBP wGRS and AS (MR-Egger intercept estimate  $p=0.015$ ), which was no  
505 longer significant after removing 6 of 37 SNPs appearing as outliers from the leave-one-out  
506 analysis (**Methods**), leading to causal estimates in broad agreement across regression  
507 techniques (**Supplementary Table 15**).

508

### 509 **Shared genetic contribution to stroke and related vascular traits at the whole genome** 510 **level**

511 Third, we applied LD score regression to quantify the extent of shared genetic contributions  
512 between traits on a whole genome level.<sup>33,34</sup> Using available GWAS results from individuals  
513 of European ancestry, we found significant positive correlations ( $r_g > 0$ ;  $p < 5.6 \times 10^{-3}$   
514 correcting for 9 independent phenotypes), mostly corroborating the wGRS results (**Fig. 4** and  
515 **Supplementary Table 16**). In addition, we found significant genetic overlap between  
516 triglyceride levels and AIS with similar results obtained in available GWAS datasets from  
517 East-Asian ancestry (**Supplementary Table 16**). Results did not materially change when  
518 removing genome-wide signals for stroke and related vascular traits and their proxies ( $r^2 \geq 0.8$   
519 in 1000G EUR).

520

521

### 522 *Global functional interpretation of stroke risk loci*

523

### 524 **Global epigenetic patterns at the 32 stroke risk loci**

525 To test for cell-specific enrichment in chromatin marks that were previously shown to be  
526 phenotypically cell-type specific in ENCODE/RoadMap (H3K4me1, H3K4me3, H3K9ac)<sup>35</sup>,  
527 we implemented the epigwas tool<sup>35</sup> and the narrow peak information from the latest RoadMap  
528 dataset (127 tissues).<sup>36</sup> Epigwas estimates the enrichment score (ratio of the height of the  
529 nearest narrow peak over the distance to the peak) for the lead variant and proxies ( $r^2 \geq 0.8$  in  
530 1000G cosmopolitan panel) and calculates statistical significance by examining the relative  
531 proximity and specificity of the test SNP-set with 10,000 sets of matched background. The  
532 analysis showed significant enrichment of enhancer and promoter sites (H3K4me1,  
533 H3K4me3) in mesenchymal stem cells, embryonic stem cells, epithelial cells, and blood & T-  
534 cells, and of active promoters (H3K9ac) in embryonic stem cells and digestive tissue  
535 (**Supplementary Table 17**).

536

### 537 **Pathway Analyses**

538 To identify pathways overrepresented in stroke association results we used the DEPICT gene-  
539 set enrichment tool<sup>37</sup> using all SNPs with  $\log_{10}(\text{BF}) > 5$  for the respective stroke subtype. We  
540 found three gene-sets to be significantly (FDR < 5%) associated with AS: enlarged heart,  
541 decreased cardiac muscle contractility, and oxaloacetate metabolic process (**Supplementary**  
542 **Table 18**). Next, we used Ingenuity Pathway Analysis  
543 (<https://www.qiagenbioinformatics.com/products/ingenuity-pathway-analysis/>) examining

544 genes within the 53 stroke loci with  $\log_{10}(\text{BF}) > 5$ . The extended gene list ( $r^2 > 0.5$  in 1000G  
545 Europeans or East-Asians, or located within 50kB of the lead SNP) consisted of 214 genes.  
546 We found the coagulation system to be the most significant canonical pathway followed by  
547 cardiomyocyte differentiation via bone morphogenetic protein receptors (FDR 5%)  
548 (**Supplementary Table 19**). Finally, we tested enrichment of VEGAS2 derived gene-based p-  
549 values in expert curated and computationally predicted Biosystem gene-sets<sup>38</sup> adapting  
550 VEGAS2Pathway,<sup>39</sup> and identified significant association with 18 pathways including various  
551 cardiac pathways, muscle cell fate commitment, and nitric oxide metabolic process with CES  
552 (FDR 5%) (**Supplementary Table 20**).

553  
554

### 555 *Prioritizing potential causal variants*

556

#### 557 **Fine-mapping derived from credible SNP set analyses**

558 To reduce the number of candidate variants per locus to the most noteworthy associations we  
559 constructed 95% credible SNP sets for each of the 32 loci (lead SNP and proxy SNPs  $r^2 > 0.1$   
560 in 1000G panels) assuming one causal SNP per locus and uniform priors.<sup>40</sup> Credible SNP sets  
561 were generated in all stroke phenotypes and for European, East-Asian, and African ancestries  
562 separately. We found a marked reduction of credible SNP sets for most loci, expectedly most  
563 pronounced for the phenotype showing the strongest association signal (**Supplementary**  
564 **Table 21**). The greatest refinement was observed at *RGS7*, *HDAC9-TWIST1*, and *SH2B3*,  
565 where the lead SNP was the only SNP contained in the 95% credible set for the stroke  
566 phenotype showing the strongest association.

567

#### 568 **Stroke loci with nonsynonymous or predicted deleterious variants**

569 To determine SNPs that have protein-altering effects, we annotated all SNPs using  
570 ANNOVAR.<sup>41</sup> Of the 32 lead SNPs three were exonic, of which two were non-synonymous  
571 (rs3184504 [p.Arg262Trp] in *SH2B3* and rs1052053 [p.Gln75Arg] in *PMF1*). p.Arg262Trp is  
572 a loss-of function variant that leads to expansion of hematopoietic stem cells and enhanced  
573 megakaryopoiesis in humans.<sup>42</sup> Both variants are predicted to be benign or tolerated by  
574 PolyPhen<sup>43</sup> and SIFT.<sup>44</sup> In addition, we identified a proxy SNP ( $r^2=0.99$  in 1000G EUR) for  
575 another lead SNP, that was non-synonymous (rs6050 [p.Thr331Ala] in *FGA*), also predicted  
576 as benign or tolerated.

577

#### 578 **Investigation of eQTLs, meQTLs, and pQTLs in different tissues**

579 We interrogated genome-wide gene expression (expression quantitative trait loci, eQTLs),  
580 methylation (meQTLs), and protein expression (pQTLs) in extensive publicly and non-  
581 publicly available datasets to determine whether stroke risk SNPs influenced the  
582 *cis* regulation of nearby genes. These datasets encompass numerous tissues and cell types  
583 including cardiac, vascular, and brain tissue, circulating cells, and vascular endothelial cells  
584 (**Methods**). These comprise: for eQTLs the GTEx V6<sup>45</sup>, an expanded version of GRASP2<sup>46,47</sup>,  
585 HGVD<sup>48</sup>, BIOS<sup>49</sup>, Blueprint epigenome project (subset)<sup>50</sup>, STARNET<sup>51</sup> and the human aortic  
586 endothelial cells study<sup>52</sup>; for meQTLs, the Blueprint epigenome project (subset)<sup>50</sup> and the  
587 ARIC cohort<sup>53</sup>, and for pQTLs the KORA cohort.<sup>54</sup> Only *cis* eQTLs, meQTLs, and pQTLs  
588 were considered.

589 We found that in 18 of the 32 stroke risk loci the lead stroke risk variant either overlapped or  
590 was in moderate to high LD ( $r^2 > 0.8$ ) with the most significant QTL variant for a nearby gene,  
591 in at least one tissue or cell type (**Supplementary Table 22 and 23**). For seven loci, we  
592 observed association of the lead SNP and proxies with expression of a single gene (or  
593 methylation or protein level), sometimes the nearest gene (*LRCH1*, *CDK6*, *CDKN2B*, *PRPF8*,  
594 and *MMP12*), sometimes a more distant nearby gene (*ZCCHC14* for the *ZCCHC14* locus, and

595 *TWIST1* for the *HDAC9-TWIST1* locus), within the datasets we explored. Associations were  
596 mostly found in stroke-relevant tissues and cell types, including vascular tissues, aortic  
597 endothelial cells, brain, blood, and immune cells. In most instances (11 loci, 61.1%), the risk  
598 SNP affected expression of multiple genes suggesting that at individual loci pleiotropic  
599 mechanisms, which might differ according to tissue/cell type, could in some instances  
600 influence stroke susceptibility.<sup>55,56</sup> For several of these loci there was a clear predominance of  
601 eQTL associations with one gene in stroke-relevant tissues, such as *ZNF318* (chr6p21),  
602 *AL049919* (chr12q24), and *FES* (chr15q26) in brain tissues (**Supplementary Table 22-23**).  
603 At some loci, meQTLs and eQTLs provided complementary information on the regulatory  
604 pattern. For instance, for the *SH3PXD2A* locus, SNPs in high LD with the lead stroke risk  
605 variant are eQTLs for multiple genes (*SH3PXD2A*, *SLK*, *GSTO1*, *GSTO2*, *LOC729081*),  
606 while several high LD proxies ( $r^2 > 0.96$ ) function as the most significant meQTL for CpG  
607 probes located in the promoter region of *SH3PXD2A* and not any of the other genes.  
608 For the 149 genes located in the 32 genome-wide significant loci ( $r^2 > 0.5$  in Europeans or  
609 East-Asians, or being located  $\pm 50$ kb from the lead SNP, **Methods**), we assigned an empirical  
610 functional score based on the presence and number of eQTLs, meQTLs, pQTLs and other  
611 biological criteria<sup>57,58</sup> (**Methods and Supplementary Table 24**) reasoning that genes with a  
612 higher functional score are more likely to be causal, although this score requires validation by  
613 experimental data.

614

### 615 **Joint modeling of epigenetic marks and association statistics**

616 As an additional approach to identify the most plausible causal variants and genes we used  
617 RiVIERA<sup>59</sup>, which jointly models summary association statistics and corresponding  
618 epigenetic regulatory information in a Bayesian framework to estimate the posterior  
619 probability of association (PPA). RiVIERA uses the RoadMap epigenome data of 127 tissue  
620 types and information on chromatin (H3K4me1, H3K4me3, H3K36me3, H3K27me3,  
621 H3K9me3, H3K27ac, H3K9ac), and DNA accessibility (DNaseI) marks. Three of the stroke  
622 risk loci (*PMF1-SEMA4A*, *SH3PXD2A*, and *EDNRA*) displayed a pattern in which the  
623 association statistics and epigenetic regulatory information jointly contributed to the modeling  
624 of the RiVIERA credible SNP set (the minimum number of SNPs whose PPA, accounting for  
625 both association statistics and epigenetic regulatory information, sum up to  
626  $\geq 95\%$ ) (**Supplementary Fig. 13**). The variants identified by RiVIERA as having the highest  
627 PPA were in moderate to high LD in the 1000G cosmopolitan panel with the respective lead  
628 SNP (rs7534434 for *PMF1-SEMA4A* [ $r^2=0.79$  with lead SNP]; rs11191829 for *SH3PXD2A*  
629 [ $r^2=0.99$ ]; rs4835084 for *EDNRA* [ $r^2=0.35$ ]). Two of these (at *PMF1-SEMA4A* and  
630 *SH3PXD2A*) were significantly enriched for RNA Pol II binding in ENCODE cell types<sup>60</sup>  
631 including H1-hESC (human embryonic stem cells) (**Supplementary Fig. 13**).

632

### 633 **Enrichment in drug target genes**

634 Given previous evidence for utility of GWAS for drug discovery and drug repositioning<sup>57,61,62</sup>  
635 we evaluated the overlap between stroke-associated genes and known drug targets. Among  
636 the 149 genes located within the 32 stroke risk loci, 16 (11%) were registered as targets of  
637 currently approved drugs in the DrugBank database and the Therapeutic Target Database  
638 (**Supplementary Table 25**). Of these, two genes (*FGA*, *PDE3A*) were targets of approved  
639 drugs for antithrombotic therapy (ATC B01), i.e. alteplase, tenecteplase, reteplase and  
640 anistreplase for *FGA*, and cilostazol for *PDE3A* (enrichment OR=5.46,  $p=0.0369$ ; **Fig. 5**).  
641 This enrichment was strengthened after removing the locus with the largest number of genes  
642 (*SH2B3*, 73 genes) (OR=8.89,  $p=0.0166$ ) and after adding 65 genes in 21 suggestive stroke  
643 risk loci (OR=7.83,  $p=0.00606$ ).

644

645

## 646 DISCUSSION

647

648 The current transethnic meta-analysis more than triples the number of stroke risk loci and  
649 identifies novel loci for AS, AIS, and all major subtypes of ischemic stroke. Our results  
650 highlight several major features of stroke genomics: (i) approximately half of the identified  
651 stroke loci show shared genetic association with other vascular traits, the largest genetic  
652 correlation being found for BP. We also identified shared genetic association with VTE, with  
653 distinct patterns for individual stroke subtypes providing mechanistic insight; (ii) eleven of  
654 the novel stroke loci (*ANK2*, *CDK6*, *KCNK3*, *LINC01492*, *LRCH1*, *NKX2-5*, *PDE3A*, *PRPF8*,  
655 *RGS7*, *TM4SF4-TM4SF1* and *WNT2B*) point to mechanisms not previously implicated in  
656 stroke pathophysiology; some of these suggest a strong link with cardiac mechanisms beyond  
657 those expected from established sources of cardioembolism; (iii) the 32 stroke risk loci were  
658 significantly enriched in drug targets for antithrombotic therapy, one for an approved  
659 thrombolytic drug (alteplase) and the other for an antiplatelet agent (cilostazol) approved for  
660 stroke prevention in Asia; (iv) through incorporation of extensive functional datasets and  
661 bioinformatics analyses we provide detailed information on prioritization of stroke risk  
662 variants and genes as a resource for further experimental follow-up.

663 The majority of genome-wide associations were identified with both AS and AIS. While this  
664 relates in part to a higher power compared to subtypes, we also found shared genetic  
665 influences between stroke subtypes, as exemplified by the gwas-pw analyses (*SH2B3* and  
666 *ABO*). A notable finding is the identification of *PMF1-SEMA4A* as a risk locus for AIS.  
667 *PMF1-SEMA4A* is an established risk locus for non-lobar ICH<sup>6</sup> and thus represents the first  
668 locus reaching genome-wide significance for ischemic as well as hemorrhagic stroke. *PMF1-*  
669 *SEMA4A* further reached genome-wide association for WMH burden<sup>28</sup> (**Fig. 3**), an established  
670 marker for SVD, and showed a strong signal in the SVS subtype suggesting that the  
671 association with stroke is at least in part mediated by SVD. The underlying biological  
672 pathways do not seem to involve known vascular risk factors and may thus reveal novel  
673 targets for stroke prevention.

674 Among the novel loci showing associations restricted to specific stroke subtypes, *EDNRA* is  
675 consistent with atherosclerotic mechanisms given its association with LAS, cPL<sup>27</sup> and CAD<sup>31</sup>  
676 (**Fig. 3**). *LINC01492* and the previously reported *TSPAN2* locus likewise displayed  
677 associations restricted to LAS but showed no association with related phenotypes in our look-  
678 ups and in prior literature, thus evidencing mechanisms more specific for LAS. *NKX2-5*,  
679 showing association restricted to CES, was previously reported as a genome-wide risk locus  
680 for heart rate and PR interval<sup>63,64</sup> but not consistently for AF<sup>63,65</sup> thus pointing towards cardiac  
681 mechanisms other than AF.

682

683 Although the number of loci reaching genome-wide significance for association with SVS  
684 remains low, our results suggest an important role for common genetic variation in SVS. First,  
685 several of the associations with AS or AIS including at novel loci (*CASZ1*, *LOC100505841*,  
686 *SH3PXD2A*, *ICAIL-WDR12*) show predominant association with the SVS subtype  
687 (**Supplementary Table 7** and **Supplementary Table 9**). Second, three of the top loci  
688 (*PMF1-SEMA4A*, *LOC100505841*, *SH3PXD2A*) show genetic overlap with loci for WMH.  
689 Third, several suggestive loci ( $\log_{10}[\text{BF}] \geq 5$ ) for AS and SVS harbor genes implicated in  
690 monogenic SVD (*HTRA1*, *COL4A1*, *COL4A2*) (**Supplementary Table 8**).

691 Our extensive exploration of shared genetic variation between stroke and related vascular  
692 traits found the most widespread correlations with BP phenotypes consistent with  
693 epidemiological data showing high BP to be the leading risk factor for stroke. A quarter of the  
694 32 genome-wide significant stroke loci are BP loci, most of which are novel with respect to

695 stroke risk and show association with risk of AS or AIS. Aside from expected genetic overlap  
696 between LAS and CAD, we also identified significant overlap between a wGRS for VTE and  
697 both LAS, and CES, but not SVS (**Supplementary Table 14, Fig. 4**) despite a higher power  
698 for this subtype, potentially suggesting that thrombotic processes play a less important role in  
699 SVS.

700 Three of our novel loci (*NKX2-5*, *ANK2*, and *LRCH1*) have previously been associated with  
701 cardiac pacing.<sup>63,64,66</sup> *NKX2-5* and *ANK2* are further implicated in familial forms of cardiac  
702 disease<sup>67-70</sup> but none of the three loci was associated with AF or CAD in the latest published  
703 GWAS.<sup>31,65</sup> Apart from *NKX2-5* they were not specifically associated with CES, possibly  
704 pointing to an involvement of the underlying genes beyond cardiac development and function.  
705 rs9526212, the lead variant in *LRCH1* functions as an eQTL for *LRCH1* in multiple tissues  
706 including left ventricle, atherosclerotic aorta, atherosclerotic-lesion free arteries, and blood  
707 (**Supplementary Table 22**). Pathway analyses further support a strong link with cardiac  
708 mechanisms.

709  
710 The extensive in silico functional annotation of identified stroke risk loci provides informative  
711 elements for future prioritization and follow-up of the most compelling biological candidates.  
712 In some instances, the eQTL, meQTL and pQTL information strongly supports involvement  
713 of one gene over others in the region, e.g., for *SH3PXD2A*, encoding SH3 and PX domain-  
714 containing protein 2A, an adapter protein involved in invadopodia and podosome formation as  
715 well as extracellular matrix degradation. For some loci, joint analysis of epigenetic regulatory  
716 effects and association statistics enabled prioritization of credible SNPs. When exploring  
717 overall epigenetic patterns of identified stroke risk loci, some enrichment of enhancer and  
718 promoter sites in developmental tissues was observed, suggesting that some associations may  
719 be driven by developmental effects, as recently proposed for the *FOXF2* locus.<sup>10</sup>

720  
721 *RGS7* and *TM4SF4-TM4SF1* showed low minor allele frequencies, high heterogeneity, poor  
722 imputation quality in non-Europeans, and large effect size estimates and must therefore be  
723 interpreted with caution. Moreover, while our extensive functional exploration provides  
724 guidance on gene prioritization for further exploration, additional experiments are required to  
725 identify the causal genes and variants. Several studies had limited information on stroke  
726 subtypes. Hence sample sizes for ischemic stroke subtypes were still in the lower range. Also,  
727 the proportion of the phenotypic variance explained by the 32 lead SNPs was relatively small  
728 but comparable to other complex diseases.<sup>71</sup> Collectively, these aspects highlight the potential  
729 for gene discovery in the future.

730  
731 In conclusion, we identify 22 novel stroke risk loci and demonstrate shared genetic variation  
732 with multiple related vascular traits. We further identify novel loci offering mechanisms not  
733 previously implicated in stroke pathophysiology and provide a framework for prioritization of  
734 stroke risk variants and genes for further functional and experimental follow-up. Stroke risk  
735 loci are significantly enriched in drug targets for antithrombotic therapy thus highlighting the  
736 potential of stroke genetics for drug discovery. Collectively, these findings represent a major  
737 advance in understanding the genetic underpinnings of stroke.

**Author Contributions**

R.M., G.C., M.T., M.S., Y.O., S.D. and M.D. wrote and edited the manuscript. Study design/conception: R.M., M.D., S.D., B.M.P., G.J.F, J.W.J., J.I.R., J.G.W., M.F., H.I.Y., C.J., S.S., W.T.L. O.M.; Statistical analysis: G.J.F.,M.F.,Y.O.,R.M.,M.S.,M.T.,A.M.,E.G.H.,C.D.A.,T.M.B.,C.C.,I.C.,W.Y.L.,S.L.P.,K.Ra.,K.R.,S.T.,J.C.,F.T.; Sample/phenotype contribution: M.D., S.D., C.D.A., C.C., I.C., H.I.H., J.W.J., N.S.R., B.M.P, J.I.R., J.G.W., O.M., C.J., J.C.H., S.S., T.A., G.B.B., R.D.B., A.H., N.L.S., R.L., C.M.L., T.N., P.M.R., V.S., C.O.S., P.S., C.L.M.S., K.D.T., S.T., M.C., D.S., I.F., J.H.; Critical revision of article: R.M., M.D., S.D., B.M.P., C.J., J.I.R., O.M., S.S., G.J.F., J.W.J., W.T.L., C.D.A., D.S., E.G.H., I.F., S.T., C.L.M.S., C.O.S., C.C., G.B.B., I.C., J.C.B., J.H., K.R., S.L.P., N.S.R., S.S.R., T.A., T.N., J.M.M.H, T.M.B., V.S.; Supervision: M.D., S.D., C.D.A., J.M.M.H , J.I.R., S.S., C.M.L., C.L.M.S., J.W.J., V.S., J.C.B; GWAS analyses: R.M., G.C., M.T., S.G., G.T., J.H., A.K.G., M.C., J.B., C.C., A.H., G.J.F., Y.K. Functional annotation: M.S., A.M., R.M., G.C., M.T., L.R.J., A.K.G.; Gene-based analysis: A.M.; Pathway analyses: A.M., R.M., M.C., K.R.; Drug Target Analysis: Y.O.; Scoring method: M.S., R.M., S.D., M.D.; wGRS analysis: M.S., R.M.; LD score regression analysis: R.M., M.S., Y.K.; credible SNP set analysis: R.M., G.C., M.S.

**Competing financial interests**

S.G., G.T., U.Th. and K.S. are all employees of deCODE Genetics/Amgen, Inc.; M.A.N. is an employee of Data Tecnica International; P.T.E is the PI on a grant from Bayer HealthCare to the Broad Institute focused on the genetics and therapeutics of atrial fibrillation; S.A.L receives sponsored research support from Bayer HealthCare, Biotronik, and Boehringer Ingelheim, and has consulted for St. Jude Medical and Quest Diagnostics; E.I. is a scientific advisor for Precision Wellness, Cellink and Olink Proteomics for work unrelated to the present project; B.M.P. serves on the DSMB of a clinical trial funded by Zoll LifeCor and on the Steering Committee of the Yale Open Data Access Project funded by Johnson & Johnson. The remaining authors have no disclosures.

**Disclaimer:** The views expressed in this manuscript are those of the authors and do not necessarily represent the views of the National Heart, Lung, and Blood Institute; or the National Institutes of Health.

1113 **FIGURE LEGENDS**

1114  
1115 **Figure 1** MEGASTROKE study design. Variants were retained that passed central QC  
1116 criteria (Methods). Number of cases / number of controls are listed for each ancestry. 1000G,  
1117 1000 Genomes; HRC, Haplotype reference consortium; MAF, minor allele frequency; rsq,  
1118 squared correlation between imputed and true genotypes; imp, measure of imputation quality  
1119 (Methods); FE, fixed-effects; EUR, European ancestry; AFR African ancestry; EAS, East  
1120 Asian ancestry; SAS, South Asian ancestry; ASN, mixed Asian ancestries; LAT, Latin  
1121 American ancestry.  $P_{het}$ , heterogeneity p-value;  $PP_{het}$ , posterior probability of heterogeneity. \*  
1122 Note the ASN and LAT ancestries were composed of a single study so did not require  
1123 ancestry specific meta-analysis.

1124  
1125 **Figure 2** Association results of the transethnic GWAS meta-analysis and the prespecified  
1126 ancestry-specific meta-analysis in European samples. Shown are novel (red) and replicated  
1127 (black) genetic loci associated with any stroke or stroke subtypes. The upper panel displays  
1128 the Manhattan plot from the MANTRA transethnic GWAS meta-analysis for any stroke. The  
1129 dotted line marks the threshold of statistical significance ( $\log_{10}(\text{Bayes factor}) > 6.0$ ).

1130  
1131 **Figure 3** Genetic overlap between stroke and related vascular traits at the 32 genome-wide  
1132 significant loci for stroke. (A) Association results from the look-ups in published GWAS data  
1133 for related vascular traits. Symbol sizes reflect p-values for association with the related trait.  
1134 (B) Venn diagram. Loci reaching genome-wide significance for association with stroke  
1135 subtypes are marked by a dagger symbol (for CES), underlined (for LAS), or marked by an  
1136 asterisk (for SVS). Novel loci are in bold. Note that *SH3PXD2A*, *WNT2B*, *PDE3A* and  
1137 *OBFC1* have previously been associated with AF (*SH3PXD2A*)<sup>65</sup>, DBP (*WNT2B* and  
1138 *PDE3A*)<sup>24,88</sup> or SBP (*OBFC1*)<sup>89</sup>, but the respective lead SNPs were in low LD ( $r^2 < 0.1$  in  
1139 1000G cosmopolitan panel) with variants associated with stroke in the current GWAS. MRI,  
1140 magnetic resonance imaging; CAD, coronary artery disease; IMT, intima-media thickness.  
1141 BP, blood pressure; LDL, low density lipoprotein; HDL, high density lipoprotein. Note that  
1142 the lead variant for *TBX3* is not included in the original data sets for BP traits (SBP and  
1143 DBP). Results are based on a perfect proxy SNP (rs35432,  $r^2 = 1$  in the European 1000G phase  
1144 3 reference).

1145  
1146 **Figure 4** Shared genetic contribution between stroke and related vascular traits as determined  
1147 by weighted genetic risk scores (wGRS, upper panel) and LD score regression analysis (lower  
1148 panel). Effect sizes and significance levels are represented by color and symbol size.  $\beta$ , wGRS  
1149 effect size;  $R(g)$ , genetic correlation. Sample sizes for related vascular traits are displayed in  
1150 Supplementary Table 12.

1151  
1152 **Figure 5** Connection between stroke risk genes and approved drugs for antithrombotic  
1153 therapy. Shown are the connections between lead SNPs at stroke risk loci, biological stroke  
1154 risk genes, and individual targeted drugs. Lead SNPs reaching suggestive evidence for  
1155 association (MANTRA transethnic meta-analysis  $\log_{10}(\text{Bayes factor}) > 5$ ) are shown in grey.

| rsID                      | Chr   | Gene(s)               | Location relative to gene | Risk allele/reference allele | Risk allele frequency, % | Phenotype | Analysis | OR   | 95% CI    | P-value  | log10 (BF) |

1156 **Table 1** Results from the transethnic and fixed effects (transethnic and Europeans-only) GWAS meta-analyses. For each locus the variant reaching the highest BF in the MANTRA or the  
1157 lowest p-value in the fixed effects transethnic meta-analysis or the fixed effects Europeans-only meta-analysis, respectively, is shown and the respective stroke phenotype showing the  
1158 strongest association is specified. Gene names in bold indicate that the variant is located within the gene; in other cases the first gene corresponds to the closest gene, whereas additional  
1159 gene names indicate eQTL signals from multiple studies, or from both eQTLs and meQTLs, or genes previously suspected to be causal (LDLR) with a maximum of two genes reported.  
1160 Note that the lead SNPs in *ILF3-SLC44A2* and *SMARCA-LDLR* are in low LD ( $r^2=0.082$ ). Chr, chromosome; TRANS, MANTRA transethnic meta-analysis; EUR, Europeans-only fixed-  
1161 effects meta-analysis; OR, odds ratio; CI, confidence interval; BF, Bayes factor; NA, not assessed; \* rs146390073 did not meet the MAF threshold of 0.01 in samples other than those of  
1162 European ancestry; \*\*rs7610618: The trans-ethnic meta-analysis results showed high heterogeneity ( $PP_{het}=0.96$ ) and were thus excluded

## ONLINE METHODS

### *Study design and phenotyping*

A detailed description of the study design, participating studies, and phenotype definitions for stroke and stroke subtypes is provided in the **Supplementary Note**. Characteristics of study participants are given in **Supplementary Table 2** for each study. All participants provided written informed consent, and local research ethics committees and institutional review boards approved the individual studies.

### *Genotyping, imputation and quality control*

Genotyping platforms and imputation methods for each participating study are described in **Supplementary Table 2**. All studies used imputed genotypes based on at least the 1000Genomes phase 1 multiethnic reference panel and conducted logistic regression analyses (or Cox regression for longitudinal population-based cohort studies) for five stroke traits (AS, AIS, LAS, CES and SVS) with all measured and imputed genetic variants in dosage format using appropriate software under an additive genetic model with a minimum of sex and age as covariates. Information on additional covariates is given in **Supplementary Table 2**. Before ancestry-specific meta-analysis, quality control (QC) was performed on each study by two independent researchers following a standardized protocol based on the suggestions of Winkler et al.<sup>72</sup> Marker names and alleles were harmonized across studies. Meta-analyses were restricted to autosomal biallelic markers from the 1000Genomes phase1 v3. Duplicate markers were removed from each study. P-Z plots, QQ-plots and allele-frequency-plots were constructed for each study. After visual inspection, analysis and QC was repeated if deemed necessary. QC was conducted independently for all participating studies in at least two sites. Individual study-level filters were set to remove extreme effect values ( $\beta > 5$  or  $\beta < -5$ ), rare SNPs ( $MAF < 0.01$ ) and variants with low imputation accuracy ( $oevar\_imp$  or  $info$  score  $< 0.5$ ). Effective allele count was defined as twice the product of minor allele frequency, imputation accuracy ( $r^2$ ,  $info$  score or  $oevar\_imp$ ), and number of cases. Variants with an effective allele count  $< 10$  were excluded.<sup>72</sup> The number of SNPs passing QC for each study is given in **Supplementary Table 26**.

### *Genome-wide Association Meta-Analyses*

The overall analytical strategy is shown in **Figure 1**. We conducted fixed effects inverse variance weighted meta-analysis with METAL<sup>73</sup>, first in each ethnic group (EUR, EAS, AFR, SAS, LAT, and other ASN), followed by meta-analysis of ancestry-specific meta-analysis results. We constructed two versions of each meta-analysis: one with single genomic control (GC) applied and one without GC (for LD score regression analysis).

The EUR specific and transethnic fixed effects meta-analysis were further filtered for heterogeneity ( $p\_het < 5.0 \times 10^{-8}$ ) and for the number of cases included for a specific marker ( $< 50\%$  of stroke cases were excluded). In addition, we ran a transethnic GWAS meta-analysis using MANTRA.<sup>15</sup> The latter was based on ancestry-specific meta-analysis results. Final MANTRA results were filtered for a MANTRA posterior probability heterogeneity p-value  $< 0.95$ . SNPs with  $\log_{10}(BF) > 6$  were considered to be genome-wide significant, whereas SNPs with  $6 > \log_{10}(BF) > 5$  were considered to show suggestive association. We used a method based on summary statistics<sup>74</sup> to estimate the variance in liability explained by each lead variant. Disease prevalence was set to 5.5% for AS, to 4.4% for AIS and to 0.11% for IS subtype in Europeans.<sup>75</sup> Disease prevalence was set to 2.97% for AIS, to 0.91% for LAS, to 0.24% for CES and to 1.76% for SVS in East-Asians (unpublished data from the Hisayama study). We used summary statistics from the Europeans-only fixed-effects meta-

analysis and the East-Asian-only fixed-effects meta-analysis. Genomic inflation was calculated as lambda, using the GenABEL package (available through CRAN repositories). In addition, we calculated the LD score regression intercepts for the Europeans-only fixed effects meta-analysis using European LD scores.

### ***Shared genetic influences of individual loci on mechanistically defined stroke subtypes***

We used gwas-pw<sup>22</sup> to detect shared genetic influences of LAS, CES and SVS, aiming to identify genetic variants that influence respective pairs of these traits. Gwas-pw estimates the posterior probability (PPA) for four models. Model 3 is the model where a given genomic region contains a genetic variant that influences both traits. We used the fixed-effects transethnic meta-analysis results as input, transforming results into signed Z scores based on p-value and sign of the log(OR). Chunk size (number of SNPs included in each chunk analyzed) was set automatically using an approximately independent block file (ld-select) as provided by the software. Correlation was set to reflect the overlap in controls. We deemed results of model 3 with a PPA > 0.9 as significant.<sup>22</sup>

### ***Conditional analysis***

We used GCTA-COJO<sup>76</sup> to perform conditional association analysis in each of the stroke loci in Europeans. We first fit a step-wise joint regression model including all SNPs with joint p-values < 5.0 x 10<sup>-8</sup>. In instances where regions included only one SNP, we fit a model including the top 2 SNPs from each region. The models made use of (i) summary statistics from the Europeans-only meta-analysis presented herein and (ii) genotype data for 3,291 stroke cases and 11,820 controls of North European ancestry from NINDS-SIGN as an LD-reference for each region.

### ***Gene-based analysis***

We performed gene-based tests using the VEGAS approach<sup>77</sup> implemented in the VEGAS2 software.<sup>16</sup> We used 24,769 autosomal refseq genes to perform gene-based association studies. We used 1000 genomes phase 3 super populations African (AFR), East-Asian (EAS), European (EUR), American (AMR) and South-Asian (SAS) as a reference to compute pairwise LD between variants residing within a gene to perform gene-based association tests. We performed gene-based tests using ‘-top 10’ parameter in VEGAS2, which tests enrichment of top 10% of association p-values within a gene. To maintain specificity whilst including cis-regulatory variants, we included variants that are located within 10kb of a gene’s 3’ and 5’ untranslated region (UTR). We performed 1 x 10<sup>6</sup> simulations to compute empirical p-values association with each gene. For genes with p-value less than 1 x 10<sup>-5</sup> we increased the number of simulations to 1 x 10<sup>8</sup> to increase the accuracy of the association p-values. For individual stroke subtypes, we performed ancestry-specific gene-based association followed by meta-analysis of gene association p-values using Stouffer’s method, based on sample size.

### ***Association of individual stroke risk variants with related vascular traits***

We systematically explored genetic overlap with AF, CAD, cIMT, cPL, diastolic BP, systolic BP, HDL-cholesterol levels, LDL-cholesterol levels, triglyceride levels, T2D, VTE and WMH. First, we acquired summary statistics from the appropriate consortia (**Supplementary Table 12**). For each of the non-stroke phenotypes we constructed a SNP set including the index variant of the non-stroke phenotype with p-value < 1.3 x 10<sup>-4</sup> plus all variants in high LD (r<sup>2</sup> in 1000G EUR > 0.9 with this index variant). If the MEGASTROKE lead SNP was included in this set of SNPs we deemed the overlap with the non-stroke phenotype to be significant. We show two different tiers: i) variants that showed genome-wide significance in the related vascular trait (p < 5.0 x 10<sup>-8</sup>) and ii) variants that were not genome-wide significant but passed Bonferroni correction (p=1.3 x 10<sup>-4</sup>).

### ***Association of genetic risk scores of related vascular traits with stroke and stroke subtypes***

Genetic risk scores generated from variants that are shown to be genome-wide associated with various vascular risk factors (VTE, DBP, SBP, mean arterial pressure [MAP], pulse pressure [PP], HTN, HDL-cholesterol, LDL-cholesterol, TG, T2D, CAD) were used to estimate the overlap between vascular traits and stroke and its subtypes. The effect allele for each risk factor variant was defined as the allele associated with increase in the risk factor levels. Corresponding allele information, beta-coefficient and the standard error from different stroke subtypes was extracted and used as input. Association was tested using the inverse-variance weighting (IVW) method implemented as an R package “gtx V 0.0.8” (available through CRAN repositories).

We further conducted a sensitivity analyses using the MR-Egger method implemented as an R package (TwoSampleMR, available through CRAN repositories),<sup>78</sup> which unlike the IVW method estimates the intercept term as part of the analysis. An intercept term significantly differing from zero suggests the presence of directional pleiotropy. We used a conservative significance threshold of  $p < 0.05$  for the intercept. In the presence of directional pleiotropy, leave-one-out analysis was carried out by re-testing the association of the vascular GRS with the outcome (stroke) leaving out each SNP in turn, to determine whether a single SNP is driving the association. We manually identified outlier SNPs that may be driving the observed directional pleiotropy and we repeated the analyses (IVW and MR-Egger) after excluding the variants exhibiting directional pleiotropy.

The selection of SNPs for the vascular GRS is based on literature (Pubmed) search and the GWAS catalog (<http://www.ebi.ac.uk/gwas/>) identifying studies that performed GWAS of the various risk factors. The latest and largest GWAS of each risk factor was selected and the associated variant details were retrieved. For the GRS analysis only independent variants ( $r^2 < 0.01$ , based on 1000G EUR panel) were used for the analysis (**Supplementary Table 27**). Risk variant selection for BP traits (SBP, DBP, MAP and PP) was further extended to studies with gene-centric chips. We used beta-coefficients extracted from the summary statistics of the International Consortium of BP GWAS<sup>79,80</sup> as weights for this GRS analysis. A p-value of  $< 5.6 \times 10^{-3}$  correcting for 9 independent phenotypes was considered significant. The number of independent vascular phenotypes, taking into account correlation between the phenotypes considered, was estimated based on individual level data from the 3C study using the online tool matSpDlite (<http://neurogenetics.qimrberghofer.edu.au/matSpDlite/>).

### ***Shared genetic contribution to stroke and related vascular traits at the whole genome level***

We used LD score regression to estimate the genetic correlation between stroke and related vascular traits.<sup>33,34</sup> We conducted analyses on the European and East-Asian stroke GWAS summary statistics only. Summary statistics from the GWAS meta-analyses for vascular risk factors and intermediate or related vascular phenotypes (BP, blood lipids, T2D, cIMT, cPL, AF, VTE, CAD, WMH) were acquired from the respective consortia, as detailed in **Supplementary Table 12**. For LD-score regression in East-Asians we further received access to unpublished summary statistics of GWAS for blood lipids conducted in BioBank Japan, as described in the **Supplementary Note**. For each trait, we filtered the summary statistics to the subset of HapMap 3 SNPs to reduce the potential for bias due to poor imputation quality. Analyses were performed separately using summary statistics from the European and East Asian-specific meta-analysis. We used the European or East-Asian LD score files calculated from the 1000G reference panel and provided by the developers. A p-value of  $< 5.6 \times 10^{-3}$  correcting for 9 independent phenotypes was considered significant. All analyses were performed using the ldsc package (<https://github.com/bulik/ldsc>).

### ***Global epigenetic patterns at the 32 stroke risk loci***

We used the epigwas tool<sup>35</sup> to test for cell-specific enrichment in chromatin marks that were previously shown to be phenotypically cell-type specific in ENCODE and/or RoadMap epigenome data (H3K4me1, H3K4me3, H3K9ac)<sup>35</sup>, leveraging the recent release of ENCODE/RoadMap epigenome data from 127 tissue types.<sup>36</sup> Histone ChIP-seq data for narrow contiguous regions of enrichment was used to calculate the enrichment score (height of the nearest tall peak / distance to the peak) for the lead variant and proxies ( $r^2 > 0.8$  in the 1000G cosmopolitan panel). Significance was estimated by examining the relative proximity and specificity of the test SNP set with 10,000 sets (permutation) of matched background. In addition, Bonferroni correction for the number of chromatin marks tested was applied.

### ***Pathway Analyses***

To identify pathways overrepresented in the stroke association results we used Data-driven Expression-prioritized Integration for Complex Traits (DEPICT<sup>37</sup>), Ingenuity Pathway Analysis (IPA, <https://www.qiagenbioinformatics.com/products/ingenuity-pathway-analysis/>), and VEGAS2Pathway.<sup>39</sup> DEPICT version 1 rel 194, was used to identify biological pathways, tissues, and cell types enriched among suggestive associations ( $\log_{10}[\text{BF}] > 5$ ) for any stroke and stroke subtypes in the MANTRA transethnic GWAS. Results are presented for the MANTRA transethnic analysis. We deemed DEPICT pathways with an FDR  $< 0.05$  as statistically significant.

IPA Pathway analysis was conducted using an extended gene list. The latter comprised genes lying in the boundaries defined by  $r^2 > 0.5$  with the lead SNP in Europeans or East-Asians, or being located +50kB from the lead SNP, for all suggestive loci reaching  $p < 1.0 \times 10^{-5}$  or  $\log_{10}(\text{BF}) > 5$ , and consisted of 214 genes (**Supplementary Table 25**). This gene list was taken as an input for IPA, using only findings from human and experimentally verified results. Otherwise, standard parameters were used for the analysis. We corrected canonical pathway p-value with the Benjamini-Hochberg method and deemed an FDR  $< 0.05$  as significant.

We performed gene-wide gene-set enrichment analysis using the VEGAS2Pathway approach<sup>39</sup> to test which Biosystem terms<sup>38</sup> are enriched with VEGAS2 derived gene association p-values for stroke subtypes. VEGAS2Pathway performs a competitive gene-set enrichment test, while accounting for gene-density in LD blocks (or correlated association p-values of neighbouring genes), SNP density and pathway size using a resampling strategy. For individual stroke subtypes we performed separate ancestry-specific gene-set enrichment analysis. Next, we combined the gene-set enrichment association p-values across ancestry using Stouffer's method for sample size weighted combination of p-values. For each stroke subtype we tested association of 9,981 Biosystem genesets terms.

### ***Fine-mapping derived from credible SNP set analyses***

We implemented the method of Maller et al.<sup>81</sup>, converting our ancestry-specific meta-analysis p-values to Bayes factors using Wakefield's approximation<sup>40</sup>, in all stroke phenotypes in the EUR only, EAS only and AFR only analysis. We used all SNPs in LD with the lead SNP ( $r^2 > 0.1$ , ancestry-specific). The Bayes factors were then used to calculate posterior probabilities, based on the assumption of a single causal SNP in each region. For all regions, we constructed 95% credible sets of potentially causal SNPs.

### ***Investigation of eQTLs, pQTLs, meQTLs and regulatory marks in different tissues***

The following datasets, covering a large variety of tissue and cell types were interrogated for eQTLs, pQTLs, and meQTLs:

- The Genotype-Tissue Expression (GTEx-V6) project data providing significant eQTL information from 44 post-mortem tissues (449 individuals)

(<http://biorxiv.org/content/early/2016/09/09/074450>), significance is based on gene-specific p-value threshold that is permutation-adjusted for multiple SNPs per gene.

- The Genome-wide Repository of Associations between SNPs and Phenotypes build 2.0 (GRASP2),<sup>46,47</sup> as well as a collected expression and epigenetic QTL database of >100 sources covering a wide range of cell and tissue types (**Supplementary Note**), using  $p < 5 \times 10^{-6}$  as a significance threshold for association with expression of a transcript in the original study
- The Human Genetic Variation Database (HGVD)<sup>48</sup> providing eQTL information from peripheral blood cells in a Japanese population (N=1,208) with significance defined by a  $FDR < 5\%$ .
- The Biobank-based Integrative Omics Studies (BIOS) providing eQTLs from peripheral blood RNA-seq data in 2,116 unrelated individuals<sup>49</sup>, significance is defined by  $FDR < 5\%$ .
- A subset of the Blueprint epigenome project<sup>50</sup> with eQTL, meQTL and histone modification data (H3K4me1 and H3K27ac) in CD14+ monocytes, CD16+ neutrophils and CD4+ naïve T cells from 197 individuals; these were mapped using the classical QTL association test, allele-specific expression (ASE) test and the combined haplotype test, with significance defined by  $FDR < 5\%$ .
- The Stockholm-Tartu Atherosclerosis Reverse Networks Engineering Task study (STARNET)<sup>51</sup>, providing eQTL data from vascular and metabolic tissues in 600 CAD patients, with association p-values corrected by Benjamini-Hochberg ( $p < 0.05$ )
- The aortic endothelial cells study<sup>52</sup> providing eQTL data from human aortic endothelial cells in 147 individuals, with Bonferroni multiple testing correction for the number of independent SNPs ( $p < 1.0 \times 10^{-4}$ )
- The ARIC cohort<sup>53</sup> providing meQTL information from peripheral blood in 794 of European ancestry and 784 of African-American ancestry individuals from, with multiple testing correction for the number of unique CpG probes in the look-up.
- The Cooperative health Research in the region of Augsburg (KORA) cohort with pQTL information from the human blood plasma proteome<sup>54</sup> measuring 1,124 proteins on the SomaSCAN platform in 1,000 participants. Significance for each association was set at  $p < 5.0 \times 10^{-8}$ .

In each of these datasets we report the most significant *cis* QTL, meQTL, or pQTL surpassing a study-specific predefined significance level or FDR, considering only QTLs in LD with the lead stroke SNP at an  $r^2 > 0.8$  (in 1000G, as well as queries of multiple builds of SNAP<sup>82</sup> and SNiPA<sup>83</sup>), suggesting high concordance. Results are presented grouped per tissue or cell type (**Supplementary Table 23**), or per stroke risk locus (**Supplementary Table 22**). In addition, we also systematically report the association of the top QTL with stroke risk, and of the lead stroke risk variant with the corresponding transcript expression, methylation level, or protein level (**Supplementary Table 23**).

In addition we used a subset of the Blueprint epigenome project in CD14+ monocytes, CD16+ neutrophils and CD4+ naïve T cells from 197 individuals<sup>50</sup> and Haploreg V4<sup>84</sup> to annotate the lead variants and proxies for enrichment in specific histone modification marks for the chromatin state, based on CHIP-Seq data from multiple cell/tissue types from ENCODE (Encyclopedia of DNA Elements)<sup>85</sup> and NIH RoadMap epigenome.<sup>36</sup> Results for each of the lead SNPs and its proxies are displayed in detail in **Supplementary Table 22**.

### ***Integration of association statistics and in silico functional information using RiVIERA-beta***

To identify the most plausible causal variants and genes we used the RiVIERA software<sup>59</sup>, which jointly models the summary association statistics and the corresponding epigenetic regulatory information in a Bayesian framework to estimate the PPA. The empirical prior of a

variant to be associated with the respective trait through regulatory features was generated using the 848 tissue-specific epigenomic data in 7 chromatin (H3K4me1, H3K4me3, H3K36me3, H3K27me3, H3K9me3, H3K27ac, H3K9ac) and DNA accessibility (DNase I) marks from the ENCODE/RoadMap epigenome data. Binary epigenomic annotation matrices of a variant overlapping the narrow peaks were generated. For inferring the causal region, RiVIERA-beta performs a repeated (n=1,000) random sampling step per locus, with the step size set to  $1.0 \times 10^{-4}$ . Iteration is performed until the convergence (acceptance rate of > 60 %) is achieved, which is critical for the accurate estimation of PPA. We generated 95% credible sets in each region based on the PPA. Regional plots were generated using the association statistics and the PPA. Epigenetic enrichment over a fixed window size (50bp) per tissue group was generated, by taking cumulative sum of empirical prior weighted global epigenetic enrichment. Tissues were grouped into 19 groups as defined in the NIH RoadMap epigenome project.

### ***Scoring method***

In an attempt to prioritize the most likely biological candidate genes, we integrated functional and biological information into an empirical score for each of the genes residing in the 32 genome-wide significant loci. These comprised 149 genes within the region defined by an  $r^2 > 0.5$  in any of the 1000G European or East-Asian populations or physical distances of  $\pm 50$  kb from the lead SNP of the respective locus (**Supplementary Table 25**). A score of 1 was assigned for being the nearest gene to the lead SNP, for harboring a missense variant, for harboring histone marks H3K4me3, H3K9ac and H3K4me1 peaks in cells types that showed significant enrichment in epigwas analysis, and functioning as an eGene for an eQTL, meQTL, or pQTL (1 point for each) in at least one study and one tissue type. In addition, a score of 1 was assigned for each stroke phenotype showing evidence of being a drug target gene in the DrugBank database (ATC-C and ATC-B01) and the Therapeutic Target Database (**Supplementary Table 25**), and for overlap with biological pathways in DEPICT, IPA, or VEGAS2 (**Supplementary Tables 18 to 20**).

### ***Drug-Target gene enrichment analysis***

For each locus containing a variant with  $\log_{10}(\text{BF}) > 5$  in the MANTRA analysis, we annotated the genes by considering LD structures ( $r^2 > 0.5$  in any of 1KG EUR or ASN populations) or physical distances ( $\pm 50$  kbp) from the lead SNP of the respective locus. Drug target genes were extracted from the DrugBank database<sup>86</sup> (considering those registered as pharmacological "active targets; <https://www.drugbank.ca/>) and Therapeutic Target Database<sup>87</sup> (TTD; [http://bidd.nus.edu.sg/group/cjttd/TTD\\_HOME.asp](http://bidd.nus.edu.sg/group/cjttd/TTD_HOME.asp)) resulting in a list of 1,123 genes (and corresponding proteins) annotated to currently approved drugs indicated for any diseases (**Supplementary Table 25**). Drugs indicated for antithrombotic therapy (n = 69) and cardiovascular diseases (n = 324) were curated from Anatomical Therapeutic Chemical (ATC) codes (**Supplementary Table 25**). Enrichment of overlap between stroke-associated genes with drug targets for antithrombotic therapy and cardiovascular diseases were assessed by Fisher's exact test.

### **Data availability**

The datasets generated and/or analyzed during the current study are available from the corresponding authors upon reasonable request.
