Original Article Topics:	Asthma and Lower Airway Disease
News and Views Topics:	
Keywords:	epigenetics, asthma, pediatrics, epidemiology
Abstract:	**Background:** Childhood asthma is a result of a complex interaction of genetic and environmental components causing epigenetic and immune dysregulation, airway inflammation and impaired lung function. Although different microarray based EWAS studies have been conducted, the impact of epigenetic regulation in asthma development is still widely unknown. We have therefore applied unbiased whole genome bisulfite sequencing (WGBS) to characterize global DNA-methylation profiles of asthmatic children compared to healthy controls. **Methods:** Peripheral blood samples of 40 asthmatic and 42 control children aged 5-15 years from three birth cohorts were sequenced together with paired cord blood samples. Identified differentially methylated regions (DMRs) were categorized in genotype-associated, cell-type-dependent, or prenatally-primed. Network analysis and subsequent natural language processing of DMR-associated genes was complemented by targeted analysis of functional translation of epigenetic regulation on the transcriptional and protein level. **Results:** In total, 158 DMRs were identified in asthmatic children compared to controls of which 37% were related to the eosinophil content. A global hypomethylation was identified affecting predominantly enhancer regions and regulating key immune genes such as *IL4, IL5RA*, and *EPX.* These DMRs were confirmed in n=267 samples and could be linked to aberrant gene expression. Out of the 158 DMRs identified in the established phenotype, 56 were perturbed already at birth and linked, at least in part, to prenatal influences such as tobacco smoke exposure or phthalate exposure. **Conclusion:** This is the first epigenetic study based on whole genome sequencing to identify marked dysregulation of enhancer regions as a hallmark of childhood asthma.

Dear Zuzana Diamant,

Hereby, we would like to resubmit our revised manuscript. We thank the reviewers once again for their valuable comments and for their critical examination of our manuscript. We hope that we have now been able to fully address all points of criticism.

In the following, please find the specific responses to the issues raised by the reviewers.

Response to Reviewer #1:

MINOR COMMENTS

Comment 1: *For Mann-Whitney U test, it is useful to calculate the effect size. Glass rank bi-serial correlation coefficient (rg) is the appropriate method of obtaining effect size for Mann-Whitney U test.*

Reply 1:

The Glass rank biserial correlation coefficient is recommended for calculating the effect size for Mann-Whitney U (MWU) tests with an ordinal and a two-level nominal variable. In our case, the MWU was applied to metric variables (methylation beta-values or cellular composition) and a two-level nominal variable. Therefore, we report the point biserial correlation coefficient r_{bp} instead of r_g.

Figure 2C and Figure S5B were amended accordingly, as was Table S8 and the corresponding section in the main text:

"We observed an enhanced eosinophil frequency in the blood of asthmatic children (Mann-Whitney U test: Z=3.42, r_{pb}= 0.32, p= .017, Table S8), but not for the remaining cell types, i.e. B cells, T cells, monocytes, NK cells or neutrophils."

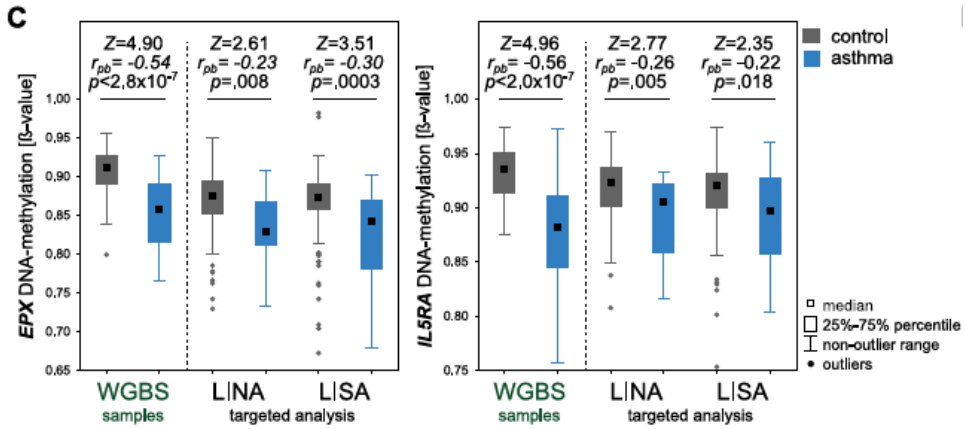

Figure 2 (C) DNA-methylation difference between asthmatic children and controls of the WGBS samples (asthma n=40, controls n=42), LINA study (asthma n=19, controls n=108) and LISA study (asthma n=25, controls n=115) for DMRs related to EPX and IL5RA as determined by sequencing or MassARRAY, respectively (p-value from Mann-Whitney U-test, rpb: point biserial correlation coefficient).

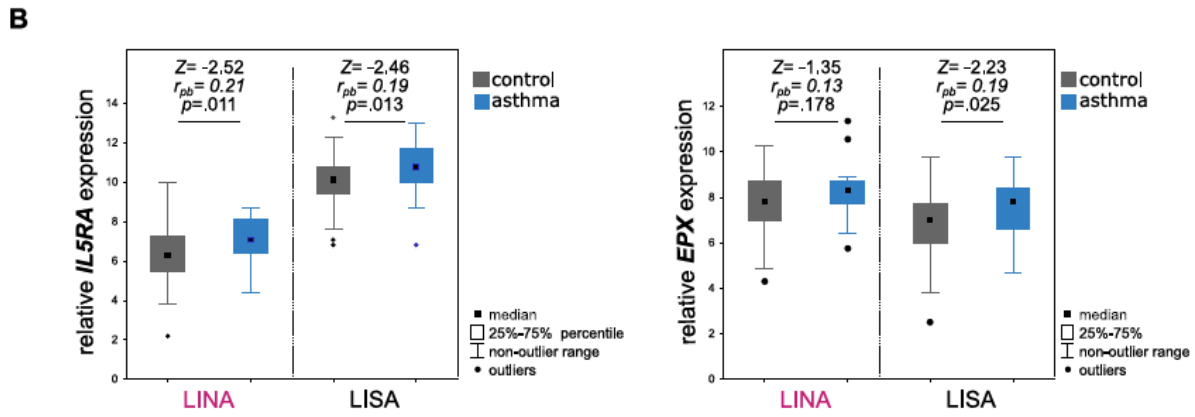

Figure S5 (B) Relative gene expression of IL5RA and EPX in asthmatic children and controls participated in LINA (asthma n=19, controls n=107) or LISA (IL5RA: asthma n=25, controls n=115, EPX: asthma n=25, controls n=113). p-value from Mann-Whitney U-test, rpb: point biserial correlation coefficient.

Excerpt of Table S8 indicating Mann Whitney U-test statistics comparing controls (n=42) vs. asthma (n=40) samples.

Cell type	control vs. asthma		
	Z	*p*-value	r_{pb} correlation coefficient
B cell	-0,37	0,715	0,057
NK	-1,03	0,316	0,056
T cell	1,1	0,273	-0,133
monocytes	-0,09	0,93	-0,012
neutrophils	-0,29	0,771	0,018
eosinophils	-3,43	0,017	0,317

Response to Reviewer #2:

Authors have adequately addressed the comments in the revised version of the manuscript. I have no further comments.

Reply 1:

We thank the reviewer for the time and effort taken to reevaluate our manuscript.

Response to Reviewer #3:

The authors have significantly improved their paper based on the extensive comments of the reviewers. There remain some limitation, but these have now adequately been addressed and discussed. I have no major comments.

MINOR COMMENTS

Comment 1: *Add the reference of SNPscore to the paper*

Reply 1:

We added the corresponding reference (The ICGC/TCGA Pan-Cancer Analysis of Whole Genomes Consortium. Pan-cancer analysis of whole genomes. Nature, 578: 82–93 (2020). DOI 10.1038/s41586-020-1969-6).

Comment 2: *IN table 1, child's sex, there is a type : Female should read 50 % but now states 0 %*

Reply 2:

We thank the reviewer for pointing this out. We corrected the typo.

Comment 3: *Part of the Supplemental table is still partly printed and appears to be out of page bounds (i.e. Table S3, from page PDF 183 onwards). Please verify this in the final version.*

Reply 3:

All supplementary tables were provided as an Excel file. Unfortunately, they were still compiled in the pdf document, which made them partly unreadable. We apologize for this inconvenience.

Sincerely,

Global hypomethylation in childhood asthma identified by genome-wide DNA-methylation sequencing preferentially affects enhancer regions

ABSTRACT

Background: Childhood asthma is a result of a complex interaction of genetic and environmental components causing epigenetic and immune dysregulation, airway inflammation and impaired lung function. Although different microarray based EWAS studies have been conducted, the impact of epigenetic regulation in asthma development is still widely unknown. We have therefore applied unbiased whole genome bisulfite sequencing (WGBS) to characterize global DNA-methylation profiles of asthmatic children compared to healthy controls.

Methods: Peripheral blood samples of 40 asthmatic and 42 control children aged 5-15 years from three birth cohorts were sequenced together with paired cord blood samples. Identified differentially methylated regions (DMRs) were categorized in genotype-associated, cell-type-dependent, or prenatally-primed. Network analysis and subsequent natural language processing of DMR-associated genes was complemented by targeted analysis of functional translation of epigenetic regulation on the transcriptional and protein level.

Results: In total, 158 DMRs were identified in asthmatic children compared to controls of which 37% were related to the eosinophil content. A global hypomethylation was identified affecting predominantly enhancer regions and regulating key immune genes such as *IL4, IL5RA*, and *EPX*. These DMRs were confirmed in n=267 samples and could be linked to aberrant gene expression. Out of the 158 DMRs identified in the established phenotype, 56 were perturbed already at birth and linked, at least in part, to prenatal influences such as tobacco smoke exposure or phthalate exposure.

Conclusion: This is the first epigenetic study based on whole genome sequencing to identify marked dysregulation of enhancer regions as a hallmark of childhood asthma.

Key words:

asthma, cord blood, DNA-methylation, prenatal exposure

INTRODUCTION

Asthma is the most common chronic inflammatory disease in childhood. With an estimated prevalence of asthma ranging from 2.6% to 30.5%[1] varying according to the age and origin of the children, childhood asthma is a major health concern worldwide. Over the last decades, the prevalence of childhood asthma increased in a majority of countries worldwide, which has been mainly attributed to an interaction of genetic predisposition with a changing environment and a Westernized lifestyle[1,2]. Although the etiology of pediatric asthma remains incompletely understood, its origin is thought to be found early in life[3]. There is a larger number of studies supporting the notion that asthma-related immune alterations are already established during the prenatal development phase when the maturation of the immune system begins[4]. Although the molecular mechanisms initiating and maintaining these aberrant immune functions are largely unknown, epigenetic mechanisms are thought to play a central role in not only mediating the adverse effects of an intrauterine environment but also in preserving the established asthma-promoting phenotype[4]. However, the knowledge of asthma-related epigenetic modifications is limited and no genome-wide studies at a single base-pair resolution are available. So far, DNA-methylation changes in asthma, have been described based on target-specific analyses or on DNA-methylation microarrays[5-9] covering 27,000-850,000 CpG sites of the approximately 28 million CpGs of the human genome.

To date, several childhood asthma-associated DNA-methylation changes at single CpG sites located in immune regulatory genes such as *ALOX12*, *IL13*, and *RUNX3*, or genes involved in arachidonic acid metabolism, T cell differentiation, and IgE production, have been described in whole blood samples[7,10]. In addition, more than 100 differentially methylated sites were identified by array-based epigenome-wide association studies (EWAS) on respiratory cells, such as buccal cells or epithelial cells of the nasopharynx, amongst others CpGs in the close vicinity of established asthma-associated genes, such as *ZFPM1*, *NLRP3*, *IFNGR2*, *NTRK1*, or

ALOX15[11-13]. However, all of the current EWAS on asthma are biased by the pre-selection of CpG sites covered by the commercially available DNA-methylation arrays.

The genomic localization of DNA-methylation changes is critical for their functional impact on gene expression and associated relevance to the disease phenotype. Perturbations in regulatory regions, and in particular enhancers regulating multiple genes, are assumed to drive disease progression[14]. Enhancers are not commonly in close vicinity of their target gene, but rather may be located several thousands of base pairs away[15]. Although previous studies of asthma-associated DNA-methylation changes provided valuable information on CpG sites potentially contributing to disease etiology and suggested an enhancer-centric epigenetic dysregulation[9], a plethora of enhancer elements have since been identified that are not covered by DNA-methylation arrays and thus have previously escaped analysis. Even with the advanced EPIC array only 7% of distal and 27% of proximal ENCODE regulatory elements, and less than 4% of all CpGs of the genome are represented[16].

As a consequence of this limited genomic coverage of previous methylation array studies only little is known about enhancer dysregulation in childhood asthma. To overcome this knowledge gap, this study used a different approach and determined the unbiased global DNA-methylation profile at a single-base pair resolution by applying whole-genome bisulfite sequencing (WGBS). Whole blood samples of 40 asthmatic children from three independent prospective birth cohorts were compared to 42 sex- and age-matched controls. It is well known that the methylation of adjacent CpG sites is mutually dependent[17] and regional changes in DNA-methylation are assumed to be functionally more relevant than single CpG positions[18]. Thus, we determined differentially methylated regions (DMRs) rather than reporting methylation changes at single CpG positions and subsequently confirmed our findings by targeted methylation analyses in larger number of cases that included subjects from two of the three cohorts. The comprehensive assessment of the genomic distribution of the DMRs was complemented by elucidating the functional consequences of aberrant DNA-methylation

associated with key immune modulating genes. To this end, cord blood - available for a subset of the children - provided the opportunity to assess potential prenatal priming of the DNA-methylation changes identified in asthmatic children.

METHODS

Detailed information can be found in the Online Supplement.

Study characteristics

This study comprises data and samples derived from the three different birth cohorts LINA[19], LISA[20], and PASTURE[21]. A detailed cohort description can be found in the Online Supplement. Participation in all three cohort studies was voluntary and written informed consent was given by the parents or children if applicable. The studies were approved by their respective ethics committees (LINA: 046-2006, 160-2008, 160b/2008, EK-BR-02/13-1, 169/13ff, 150/14ff, LISA: 398-12-05112012, PASTURE: 02046, 9/11-E1/651-2002, 415-E401/4-2007).

Asthma outcome

Asthma was defined based on the confirmative answer to the question: "Has a physician-diagnosed your child with asthma during the last 12 months (=current asthma)?" asked in the parent-reported questionnaires at the time-point when blood samples were obtained for DNA-methylation analysis.

Sample selection

From each of the three cohorts, cases and controls were randomly selected to derive a balanced selection of children diagnosed with asthma and of age- and sex-matched controls. As a prerequisite a sufficient quantitative and qualitative amount of genomic DNA had to be available. For the asthma group only children with a physician-made asthma diagnosis at the time of WGBS analysis were selected. For the control group, children were chosen who never reported wheezing symptoms, obstructive bronchitis, asthma, rhinitis or atopic dermatitis. A total of 40 children aged five to 15 years of age with a current asthma diagnosis and 42 age-

and sex-matched controls were selected for WGBS analysis. An overview of the selected samples is provided in Table S1.

For 48 children investigated at the time of an established asthma phenotype paired cord blood DNA samples were available (n=23 asthma, n=25 controls; Table S1) and also subjected to whole genome bisulfite sequencing.

Whole-genome bisulfite sequencing (WGBS)

To assess quantitative DNA-methylation information at single base pair resolution, whole blood genomic DNA samples from 82 children of the three cohorts and 48 matched cord blood samples available from LINA and PASTURE (Table S1, Table S2) were subjected to WGBS (see Online Supplement for details) as previously described[22]. All samples showed bisulfite conversion rates >99%.

Pre-processing of WBGS data

Sequencing data for each sample was input to the one touch pipeline[23] and processed using bwa v0.6.1.[24] and methylCtools v1.0.0[25] resulting in tab separated output files containing CpG position, number of reads with a methylated cytosine at this position, total number of reads covering the CpG and a *snp score*[26], which is the estimated probability of the CpG to be a SNP. CpGs were removed from the whole cohort if at least one of the 82 samples had a *snp score* of 0.25 or greater.

Determination of asthma-associated DMRs

Asthma-related DMRs were determined by a three-step procedure (i-iii). (i) DMRs were defined as at least three consecutive differentially methylated CpG sites between asthmatics (n=40) and controls (n=42). DMRs were called by two independent algorithms, a DMR calling strategy, which was applied in the latest meta-analysis on childhood asthma using 450k array data[8]. For

our WGBS data we used DSS version v2.12.0[27], and metilene version v0.2-6[28] as DMR calling tools. For DSS we used a Wald-test *p*-value threshold of .01 to mark a CpG as differentially methylated. The minimum DMR length was set to 50 bp, the maximum distance between two CpGs was set to 100 bp and the fraction of differentially methylated CpGs was set to minimum 0.3. Metilene uses circular binary segmentation followed by two dimensional Kolmogorov–Smirnov test (2D-KS test) and a DMR was considered significant if the obtained *q*-value was less than 0.05. Only chromosomes 1-22 were included in the analysis, while sex chromosomes were omitted. DSS adopts a highly appropriate beta binomial model for modelling DNA-methylation from WGBS count data but does not provide significance testing nor multiple testing correction of the identified DMRs. On the other hand, metilene offers the ability to perform multiple testing correction for the identified DMRs. Given the different approaches and features adopted by these two tools, we deemed their overlap to be highly conservative, thereby reducing potential false positives. (ii) To reduce the likelihood of false-positive DMR calls, we kept only the metilene DMRs that overlapped at least by 1 bp with the DMRs from DSS. The overlap was determined by using *intersectBed* from Bedtools version 2.24.0[29]. (iii) Concordant DMRs were tested for significance in each of the three cohorts LINA, LISA, and PASTURE by a factorial ANOVA using R version 4.0.2[30]. Log transformed β-values with a pseudo count of 0.006 of all differentially methylated CpGs within a DMR were modelled by using the disease condition asthma/control and the CpG position within a DMR. If the Bonferroni adjusted *p*-values in each of the three cohorts were $p<.05$ then a DMR was considered as significantly differentially methylated and retained for further analysis.

Overlap with previous asthma-associated EWAS

Previous asthma-associated EWAS studies in the PubMed database were identified by the search term: ("asthma" OR "wheeze") AND ("WGBS" OR "EWAS" OR "450k" OR "850k" OR "27k" OR "epigenome-wide" OR "HumanMethylation450K BeadChip") AND "blood"

(query data 27.10.2022). This search retrieved 68 publications, from which two reviews, one RCT and one systematic review were excluded. After manual curation 22 EWAS studies (including meta-analyses) remained that reported DNA-methylation changes in blood related to asthma or lung function (Figure S1A). DNA-methylation changes described in these manuscripts were related to the DMRs observed in our study.

Gene annotation and definition of enhancer and promoter DMRs

Genomic annotation of DMRs to the nearest transcription start site (TSS) from Gencode v19 gene models in human genome version hg19 was obtained by using the 'closest' module from Bedtools. Promoter regions were defined as 2 kb up- and downstream of the TSS. DMRs overlapping with at least 1 bp were categorized as promoter DMRs. DMRs were defined as enhancer DMRs, if their genomic location intersected at least 1 bp with GeneHancer[31], ENCODE[32], or ROADMAP[33] enhancer regions, or with an active histone mark as previously identified in LINA children according to Bauer *et al.*[22] (Table S3). Predicted target genes of enhancer DMRs were identified by using GeneHancer.

DMR classification

All asthma-related DMRs were classified into different categories: (i) genotype-/non-genotype-associated, (ii) cell-type-dependent, (iii) already present in cord blood. Asthma-related DMRs already present in cord blood were overlapped with previous EWAS studies investigating prenatal factors that affect DNA-methylation (see Online Supplement for details and Figure S1B).

According to previous works[19,22], a DMR was categorized as genotype-associated (gDMR) whenever a significant correlation between the methylation value of the DMR and any SNP in a +/-5 kb window around the DMR was determined (see Online Supplement for details). Likewise, DMRs with no significant association to methylation quantitative trait loci (meQTLs)

were classified as a non-genotype associated DMR (ngDMR). All meQTL SNPs were checked against the EMBL GWAS catalogue[34] (Query date: 01.11.2022) for previous associations to any phenotypic outcomes including asthma.

To determine whether the asthma-related DMRs were already differentially methylated at the time of birth, WGBS-based DNA-methylation data of matched cord blood samples were analysed (n=48, Table S1, Table S2). Whenever a DMR was significantly differentially methylated at the time of birth as determined by factorial ANOVA followed by a multiple test correction (Bonferroni-corrected $p<.05$, corresponding to a nominal $p<.00032$ separately in all three cohorts), the corresponding DMR was classified as a cord blood asthma-DMR already present at the time of birth.

To identify which cord blood DMRs were associated with a prenatal influencing factor, previously published array- or WGBS-based EWAS conducted with cord blood samples were evaluated (see Figure S1B and Online Supplement for details). This included studies on maternal smoking during pregnancy, maternal mental health, maternal disease such as diabetes and atopy, maternal BMI and diet, or environmental exposures. Whenever a CpG or region previously associated with a prenatal influencing factor overlapped with at least 1 bp with a cord blood DMR in our data set, this DMR was considered to be associated with this prenatal influencing factor.

Cell-type dependency

The frequency of the main blood cell types (T cells, B cells, NK cells, monocytes, neutrophils, eosinophils) was estimated by deconvolution of the WGBS data using *EpiDish*[35].

Next, the cell-type dependency of DMRs was determined using adjusted multiple regression models with the mean DNA-methylation of the DMR as the dependent variable and the main blood cell-type estimates as the independent variables (confounder: child's sex, cohort, prenatal tobacco smoke exposure, family history of atopy, parental school education, maternal age at

birth, growing up on a farm). DMRs significantly (Bonferroni-corrected $p<.05$, corresponding to a nominal $p<.00032$) associated to a specific blood cell type were classified as cell-type-dependent (see Online Supplement for details).

Enhancer-, pathway- and TFBS motif enrichment

We used Fisher's exact test in R to test if asthma-related DMRs were enriched for enhancer elements (Table S3) when comparing them with all other methylated regions in the genome that have similar characteristics as our DMRs but are not called as such (see Online Supplement for details).

For gene enrichment analysis the genomic positions of asthma-related DMRs were subjected to GREAT (Genomic Regions Enrichment of Annotations Tool) version 3.3.0 analysis tool[36] setting "whole genome" as background and a significance level of $\alpha<.05$.

The MEME-ChIP tool implemented in the MEME Suite version 5.4.1 (Motif-based sequence analysis tools)[37] was used to identify transcription factor binding site (TFBS) based on the HOCOMOCOv11 core HUMAN database including *de novo* motifs within the asthma-related DMRs. DMRs were elongated by 20 bp at the start and at the end to ensure an intersection with motif sequences. Only motifs with a length of four to fifteen nucleotides were considered. Motif enrichment with an *E*-value<.05 (estimate of the statistical significance of each motif) was considered significant.

Network analysis and Natural Language Processing

For network and module analysis of DMR associated genes including all enhancer DMR target genes or genes closest to the next TSS (n=435 genes) were subjected to Cytoscape analysis version 3.8.2[38]. The Reactome Functional Interaction (FI) plugin version 8.0.4 (released Feb 2022) was used to determine network patterns of common and predicted interactions as estimated via Naïve Bayes Classifier excluding linker genes. Cluster FI network was applied to

identify cluster of genes (=modules)[39]. Subsequently, a pathway enrichment analysis (significance cut-off: FDR<0.01) was performed using the databases CellMap, Reactome, KEGG, NCI PID, Panther and BioCarta for each module.

To identify genes in the network, previously associated with asthma-related outcomes, natural language processing (NLP, see Online Supplement for details) was applied. In brief, mentions of genes and gene products were searched in the PubMed and PubMed Central open access literature databases and additionally filtered by the following terms “asthma”, “asthmatic”, “asthmatics”, “wheeze”, “bronchial hyperreactivity”, “airway hyperreactivity”, “bronchial hyperresponsiveness”, or “hyperreactive airway disease”.

Targeted analyses: DNA-methylation, transcription, and protein measurement

Targeted analyses were performed in a larger sample set obtained from the 6-8 years old LINA children and the 15-years old LISA children from the Leipzig study centre. No further PASTURE samples were available for these analyses. All available samples from LINA and LISA fulfilling these two criteria were included: (i) samples from children diagnosed with asthma by a physician and (ii) control samples that never reported wheezing symptoms, obstructive bronchitis, or asthma, however they could have developed atopic dermatitis or rhinitis. An overview of the selected samples for these analyses is provided in Table S1 and Table 1B.

Targeted DNA-methylation analysis was performed for a set of selected DMRs in n=127 LINA and n=140 LISA samples using the Sequenom´s MassARRAY platform (San Diego, CA, USA, Table S4 for primer sequences, Figure S2) as previously described[22].

Functional translation of methylation changes for selected genomic regions was determined by RNA and protein expression analyses of the associated genes. Whole blood samples for transcriptional analyses were collected at the same time as blood samples for DNA-methylation analyses. RNA expression data were obtained for *EPX*, *IL4,* and *IL5RA* for n=126 LINA and

n=140 LISA samples by qPCR on the Biomark HD system as previously described[22] (see Table S5 for primer sequences).

Within the LINA study phytohaemagglutinin (PHA)-stimulated IL-4 concentrations obtained from a whole blood assay were available. IL-4 concentrations were measured by cytometric bead array (BD CBA Human Soluble Flex Set system, Becton Dickinson, Heidelberg, Germany) as previously described[40].

Detailed information can be found in the Online Supplement.

Statistics

WGBS samples

To determine potential differences in the study characteristics between asthmatic and control children a Fisher's exact- test or Mann-Whitney *U*-test were applied. As confounding factors in the models analysing WGBS-data the child's sex, cohort, prenatal tobacco smoke exposure, family history of atopy, parental school education, maternal age at birth, growing up on a farm and cell composition were included.

Targeted analyses

To test whether there were differences between asthmatic and control children of the LINA and LISA cohorts with respect to the child's age and sex, prenatal tobacco smoke exposure, family history of atopy, parental school education, maternal age at birth, growing up on a farm, or the presence of rhinitis or atopic dermatitis in the child, Fisher's exact- test or Mann-Whitney-*U* test were applied.

A Mann-Whitney-*U* test was used to determine if there were significant differences in DNA-methylation and transcription between groups. Spearman correlation was used to determine the association between DNA-methylation, relative gene expression, or protein concentration. Correlation coefficients are reported as effect size measures (point biserial (r_{pb}) for Mann-

Whitney U and Spearman's rho ρ). The selection of confounders associated with asthma or affecting DNA-methylation patterns was based on *a priori* knowledge. The child's sex, cohort, prenatal tobacco smoke exposure, family history of atopy, parental school education and maternal age at birth were introduced as confounding factors in all models.

Confounder adjusted logistic regression analyses were applied to compare the DNA-methylation and relative gene expression of asthmatic and control children. Confounder adjusted mediation analyses were performed using the *PROCESS* macro version v3.4[41] for SPSS. Statistical significance of the indirect effect was determined by bootstrapping as implemented in the *PROCESS* macro version 3.4[41]. Bias-corrected 95% confidence intervals were derived from the distribution of bootstrap estimates of the indirect effect from random resampling of 5,000 samples. Only for non-dichotomous independent variables a standardized indirect effect was calculated. Effect sizes of regression analyses are either provided as unstandardized *b*, standardized β, or as odds ratio (OR).

Statistical analyses were performed using STATISTICA for Windows Version 12.0/13.0 (Statsoft Inc. Europe, Hamburg, Germany), IBM SPSS Statistics for Windows Version 25 (IBM Corp. Released 2013. IBM SPSS Statistics for Windows, Version 22.0. Armonk, NY: IBM Corp.) or R version 4.0.2[30]. *P*-values $\leq .05$ were considered significant.

RESULTS

Genome-wide DNA-hypomethylation in childhood asthma

To evaluate epigenetic alteration in the global DNA-methylation pattern of asthmatic children at single base-pair-resolution, we performed WGBS and subsequent DMR calling of whole blood samples from n=82 children participating in the LINA, LISA, or PASTURE cohort (Figure 1, Table S1). In total, samples from n=40 asthmatic children were compared to n=42 age-matched controls without an asthma history or other respiratory symptoms (Table 1A). High quality WGBS data were derived with a mean genome coverage of 56.3x (Table S2A). To retain highly confident asthma-related DMRs for downstream analyses, a multiple-step DMR-calling approach was utilized (Figure S3). Using these two independent DMR-calling algorithms, DSS and metilene, 1,021 and 758 DMRs were determined, respectively. DMRs overlapping between these two approaches (n=385) were subjected to factorial ANOVA analysis to assess whether significant DNA-methylation differences could be observed separately in each of the three cohorts and were in the same direction. Only these concordant DMRs (n=158 out of n=385) were retained for further assessment (Figure S3, see Table S6A for asthma-related DMR list). These 158 asthma-related DMRs were distributed over all autosomes (Figure 2A) and had a read coverage of 31.5x in average (Table S2B). Unsupervised cluster analysis of these derived 158 DMRs resulted in a clear separation between asthmatics and control children (Figure S4A). The vast majority of the asthma-related DMRs were hypomethylated in asthmatic children (Figure 2A), while only two hypermethylated DMRs located in the *TET3 (ten-eleven translocation 3 or tet methylcytosine dioxygenase 3)* gene and the long coding RNA *AL645608.1* were identified. In line with previous asthma EWAS studies our DMRs overlapped with several CpG sites or DMRs identified based on array approaches (see Table S7 for overlap and references and Figure S1A for evaluated EWAS studies).

Genetic and cell type composition influences on asthma-related DMRs

Since the level of DNA-methylation can be strongly dependent on the genotype or the cell type composition, asthma-related DMRs were categorized according to cell type-dependency and genotype-association (gDMRs). Based on this categorization, 38 out of the 158 DMRs were associated with the genetic background (24.1%), while the remaining 120 DMRs (75.9%) were classified as non-genotype associated DMRs (ngDMRs). A total of 465 meQTLs were identified in relation to the 38 gDMRs, of which none has been previously described as an asthma risk factor in genome-wide association studies (Table S6B). However, including all phenotypic traits of the GWAS catalogue, we found 14 DMRs associated with at least one trait. For eight of these DMRs, the trait showed a loose phenotypic association with asthma (Table S6B) including lung function (rs645601 and rs7700998). Five SNPs were associated to counts of different blood cell types with SNPs rs4328821 and rs7646596 upstream of the *RPN1*-DMR associating to the eosinophil count. Additionally, rs12699415 related to the *MAD1L1*-DMR was linked to idiopathic pulmonary fibrosis[34].

We observed an enhanced eosinophil frequency in the blood of asthmatic children (Mann-Whitney *U* test: Z=3.42, r_{pb}=0.32, p= .017, Table S8), but not for the remaining cell types, i.e. B cells, T cells, monocytes, NK cells or neutrophils. We applied adjusted multiple regression analyses to test whether different cell type frequencies have an impact on the DNA-methylation level of the determined DMRs. To this end, 37% of the asthma-DMRs (58 DMRs) were associated with the eosinophil proportion and only three DMRs in total to B cells, T cells, monocytes, NK cells or neutrophils (Table S6A). However, even after accounting for these cell types in the adjusted multiple regression models, asthma was still a significant contributor of the DNA-methylation status for all cell-type-dependent DMRs (Table S9).

Altered DNA-methylation pattern associates with perturbed immune regulation

To elucidate the relevance of the asthma-related aberrant DNA-methylation profile, a pathway enrichment analysis was performed. Besides a strong enrichment in the asthma pathway, we

found classical immune system-related pathways enriched, such as IL-5- known to be crucial for asthma pathophysiology[42,43] (Figure 2B, Table S10). To ensure that the DNA-methylation differences observed in the small number of sequenced samples can be reproduced in larger sample numbers, targeted analyses were performed in further samples (n=267) including six to eight-years-old LINA children (n=127) and 15-years-old LISA adolescents (n=140, Table S1, Table 1B). Here, we focused on DMRs that are likely to influence aberrant immune gene expression driving asthma onset. Therefore, the DNA-methylation of two prototypical DMRs (Figure S4B) linked to genes of the asthma pathway (eosinophil peroxidase, *EPX*) - the pathway with the strongest enrichment - and the IL-5 signalling pathway (*IL5RA*) (Figure 2B) known to promote severe atopic asthma associated with eosinophilia[42], was measured in the larger sample set using a targeted DNA-methylation assay. Significant hypomethylation of these DMRs located in the sixth exon of *EPX*, and in the *IL5RA* promoter, could be confirmed in meta-analysis combining samples of the LINA and LISA cohort (adj. OR/95% CI *EPX*: 0.87/0.81-0.94, p=.0004; *IL5RA:* 0.83/0.73-0.94, p=.003, n=223 controls vs. n=44 asthmatics, Figure 2C,D) using logistic regression adjusted for the child's sex, cohort, prenatal tobacco smoke exposure, family history of atopy, parental school education and maternal age at birth. Furthermore, for both DMRs a negative correlation with the relative gene expression of the associated genes *EPX* was observed (ρ= -0.40, p=1.4x10^{-11}, n=264) and *IL5RA* (ρ= -0.32, p=1.4x10^{-7}, n=266, Figure S5A). In line, expression of *EPX* and *IL5RA* is not only increased in asthmatic children (Figure S5B) but is also associated with an increased risk for asthma during childhood (relative expression *EPX*: adj. OR/95% CI: 1.44/1.09-1.91, p=.010, n=220 controls vs. n=44 asthmatics, *IL5RA:* adj. OR/95% CI: 1.59/1.19-2.13, p=.002, n=222 controls vs. n=44 asthmatics, Figure 2D).

DNA-methylation changes in asthma affect regulatory hubs

The identified DMRs showed enrichment for 20 binding motifs related to different transcription factors previously associated with asthma including the Th2 master regulator GATA3[44] (Table S11). Additionally, two third of the DMRs were located in genomic regulatory elements, 74% of the DMRs intersecting with enhancers, and 1% with promoters (Figure 3A). In particular, the DMR enrichment in enhancer regions was highly significant (OR/95% CI: 5.83/4.05-8.53, $p<4.0x10^{-26}$). Among the DMRs overlapping with a ROADMAP enhancer active in specific blood cells (Table S3), 17 DMRs overlapped with a T helper cell-type specific enhancer including a hypomethylated enhancer DMR associated with the mTORC1 scaffolding protein coding gene *RPTOR* (Table S6A).

One of those hypomethylated enhancer regions showed an enhancer specific ENCODE histone modification profile and a ChiA-PET interaction to the *IL4* promoter (Figure 3B). Although IL4 is one of the key regulators in allergic diseases including asthma, the relevance of this particular enhancer region associated to IL-4 expression has not been addressed so far. We confirmed the asthma-related DNA-hypomethylation of this *IL4* enhancer in the meta-analysis combining the two cohorts LINA and LISA (adj.OR/95% CI: 0.83/0.74-0.94, p=.002, n=223 controls vs. n=44 asthmatics). In addition, in the LINA cohort, where IL-4 protein concentration measurements were available (Table S1), the *IL4* enhancer DNA-methylation was associated with *IL4* transcription (ρ= -.35, p=.0001) and PHA-stimulated IL-4 protein concentrations (ρ= -.31, p=0.0009, Figure 3C). In line, two confounder adjusted mediation models were applied to evaluate the relevance of this hypomethylated *IL4* enhancer region in asthma: The first model showed a significant indirect effect of *IL4* enhancer DNA-methylation on IL-4 protein concentration via *IL4* transcription as a mediator (β/95% CI: -0.07/ -0.14- -0.03, Figure 3D), whereas the direct effect was not significant (b/95% CI: -0.92/ -3.79- 1.95, p= .525). Second, the asthma phenotype contributed to an increase in IL-4 protein concentration in asthmatics again solely indirectly via the DNA-methylation changes of this *IL4* enhancer and *IL4*

transcription as mediators (Figure S6, indirect effect: *b*/95% CI: 0.05/ 0.01- 0.13; direct effect *b*/95% CI: 0.23/ -0.26- 0.73, *p*=.352).

Genes affected by DNA-methylation changes are functionally connected

To elucidate whether DMR associated genes (n=435 genes, Table S6A) were functionally connected, these genes were subjected to network analysis based on established protein-protein interactions with a subsequent pathway enrichment of the derived network modules. The resulting network consisted of 102 genes in thirteen distinct modules. These modules were related, among others, to immune response and inflammation, cilium assembly and general gene regulation, and to Jak-STAT signalling (Figure 4, Table S12). The vast majority of the network genes (97 out of 102 genes) were targets of differentially methylated enhancers. Our NLP analysis revealed that 33.3% of these enhancer target genes such as the central transcription factors of the immune system *RELA* (NFκB subunit encoding gene)*, GATA2,* and *ZFPM1,* the Th2 cytokine *IL4,* or the mTOR complex 1 scaffold protein *RPTOR* have previously been described in the literature in association with asthma (red genes in Figure 4, Table S13A). In addition, we identified novel genes not yet associated to asthma, such as the A-kinase anchoring protein-9 (*AKAP9*). *ANKAP9* is prominently expressed in T cells and involved in immune synapse formation[45]. Among the proteins interacting with ANKAP9 for its proper function are TUBGCP2/TUBGCP6, for which we also observed an enhancer DMR[46].

Prenatal priming for asthma

To discriminate between DMRs that are a consequence of the disease from those predisposing an individual, we subjected matched cord blood samples (n=23 asthmatics vs. n=25 controls) to WGBS and assessed whether the methylation changes of the 158 asthma-related DMRs were already present at time of birth (Figure 5A). 35% (56/158 DMRs) of the DMRs identified in the established asthma phenotype were already significantly differentially methylated in cord blood

samples (Table S6C). Most of the cord blood DMRs were again located in enhancers (43 out of 56), 39% (n=22/56 DMRs) were gDMRs including those already identified in GWAS as a risk factor for lung dysfunction and idiopathic pulmonary fibrosis[34] (Table S6C). For 22 out of the 56 cord blood DMRs, we found an overlap with previous EWAS studies investigating the impact of a variety of different prenatal factors on DNA-methylation (Figure S1B). These factors included exposure to tobacco smoke, to air pollution or to environmental chemicals such as phthalates or lead, maternal diet-related metabolites as well as factors related to maternal health like gestational diabetes or preeclampsia (Figure 5B, Table 13B). When focusing our network analysis on cord blood DMR associated genes the network was comprised of several members of the LFA-1 signaling pathway (Figure 5C). Next to *ITGAL* coding for one of the subunits of LFA-1 (=CD11a), also the LFA-1 ligand ICAM-1, and the co-chaperones *ANKAP9*, *TUBGC2/6* were among the target genes of DMRs already observed in cord blood.

DISCUSSION

To characterize the complete genome-wide DNA-methylation pattern in childhood asthma, this study determined the DNA-methylation profile of 40 asthmatic and 42 control children by utilizing WGBS followed by calling of differentially methylated regions (DMRs) and discriminating between genotype-, and non-genotype-associated as well as cell-type-dependent, or -independent DNA-methylation changes. In total, 158 regions were found to be differentially methylated in childhood asthma, all hypomethylated except for two, which includes a hypermethylated enhancer region for *TET*. Since TET proteins initiate DNA-demethylation, this DMR might be directly related to the global DNA-methylation aberrations observed in asthma. Whether this DMR in asthma is an initiating event or a compensatory mechanism remains to be elucidated in follow-up studies. The predominant global hypomethylation suggests a pronounced epigenetic activation affecting a variety of immune-related genes associated with asthma development and exacerbation. Here, with this first EWAS using a genome-wide sequencing approach and thus not relying on pre-selected CpGs as performed in previous asthma EWASs, we show that this epigenetic activation primarily affects enhancer elements indicating that a predominant enhancer activation underlies the exacerbated immune response characteristic of childhood asthma[47]. The tight connectivity of these epigenetically dysregulated asthma genes is evident in our inferred interaction network. A comprehensive search of the current scientific literature by NLP analytics revealed that while almost 34% of the enhancer target genes have already been associated with asthma or asthma-related terms, several of the enhancer-DMRs have not yet been discussed in the context of asthma. Most of the asthma-DMRs were enriched for multiple TFBS indicating multiple regulatory effects of the epigenetically perturbed regions. Most of the transcription factors binding to these DMR-enriched TFBS motifs are known to be associated with asthma, such as GATA3[44], NFACT1[48], IRF-1[49], GATA-6[50], STAT2[51], THB[52], or EGR1[53], and even possess a master regulatory capacity of Th2 differentiation[54,55].

LFA-1 is mainly known for its role in T cell adhesion and Th1 effector polarization. However, a recent report shows that LFA-1 and its ligand ICAM-1 are expressed on group 2 innate immune cells (ILC2). ILC2 are able to induce eosinophilic lung injury and are elevated in the blood of asthmatics compared to healthy controls[56]. Knock-down of LFA-1 or ICAM-1 both attenuated airway hyperresponsiveness, reduced airway inflammation and decreased lung ILC2 accumulation in mouse models of allergic asthma[57]. As such the observed cord blood DNA-hypomethylation of several regions involved in the LFA-1 signalling cascade might predispose children to a higher risk of allergic asthma.

The vast majority of DMRs was not associated with a meQTL indicating that mainly other than genetic factors contribute to the observed aberrant DNA-methylation in childhood asthma. About one third (35%) of the asthma-related DMRs were already found in cord blood. A variety of environmental insults experienced during the highly susceptible prenatal developmental phase - mostly related to maternal lifestyle factors during pregnancy - have been associated with an increased asthma risk of the child. A comparison to previous EWAS studies revealed that 22 of the asthma-related DMRs already identified in cord blood, including 17 differentially methylated enhancers, overlapped with DNA-methylation changes described in association to prenatal asthma risk factors (for references refer to Table S13B). Among others, these factors included maternal exposure to tobacco smoke or environmental chemicals as well as maternal health (e.g. gestational diabetes, preeclampsia). Although more studies are necessary to investigate whether these regions of persistent differential DNA-methylation are missing links between an adverse intrauterine environment and childhood asthma development, it is prudent to reduce these adverse exposures during vulnerable periods.

This study has to be seen in the light of some limitations. The sample size of whole-genome sequencing approaches seems to be low when compared to previous EWAS using less cost-intensive array based epigenetic profiling methods[5,8,58], however, in comparison to previous

WGBS studies[59-62] we included a considerable higher number of samples. In addition, the enrichment of the DMRs in the asthma pathway, the overlap between the DMR-associated genes with known asthma genes such as *IL4*, *EPX*, *IL5RA* and *ZFPM1* as identified by NLP, in conjunction with the overlap of previously reported CpG sites (e.g. *ACOT7*, *DEGS2*, *EPX* and *GATA2*) of asthma EWAS support the validity of the applied strategy to determine asthma-related DMRs. Although we confirmed the differential DNA-methylation of selected DMRs and their influence on associated target gene expression that are likely to contribute to asthma pathology in a larger sample set, further studies are needed to show whether the DMRs observed in our study can be replicated in independent cohorts and to determine the effect of the identified DMRs on the transcriptome. In addition, since more than half of the asthmatic children reported rhinitis or atopic dermatitis in their life, we cannot exclude that the observed asthma-related DMRs might also be influenced by other atopic diseases such as rhinitis or atopic dermatitis.

The whole blood-based sequencing of DNA-methylation might be seen as a further limitation. To overcome this problem, the proportion of the different cell populations was determined by a deconvolution approach and the DMRs annotated with respect to their cell-type dependency. The deconvolution approach might have led to misclassification or underrepresentation of minor cell types. However, we were able to annotate the small population of eosinophils and to show a significant difference in the eosinophil count between children with asthma and controls without respiratory disease. For a global overview of aberrant DNA-methylation changes and an unbiased interpretation of EWAS[63], we deem the here utilized approach more appropriate, i.e., not to adjust for cell-type composition beforehand, but rather to determine all DMRs and subsequently annotate them as cell-type-dependent or genotype-associated.

To our best knowledge, this is the first study evaluating the children's methylome at single base-pair resolution – including the comprehensive information on the genetic background - using repeatedly collected samples of the same individual. We were able to confirm our findings in a larger sample set of two cohorts and showed functional translation to the transcriptional and

protein level for selected DMRs. We identified global DNA-methylation changes particularly affecting enhancers, which likely contribute to an altered gene expression of key immune genes involved in asthma pathology. Most of the immune system-related epigenetic alterations including the hypomethylated *IL-4* enhancer, or the *IL5RA* promoter are not present in cord blood, supporting the notion that they are developed during the shift of the immune response toward a Th2 reactivity contributing to the development of an atopic asthma phenotype. Although most of the cord blood DMRs are not directly related to the immune dysfunction characterizing the asthmatic phenotype, these regions related to genes involved in LFA-1 signaling. In light of the emerging role of LFA-1 in ILC2 modulated allergic asthma, these cord blood DNA-methylation changes might be involved in predisposing children to a higher risk for asthma development. Future studies will show if these regions have the ability to predict high-risk children.

Acknowledgment

We cordially thank the participants of the LINA, LISA and PASTURE cohorts, as well as Beate Fink, Anne Hain, Michaela Loschinski, Melanie Bänsch and Maik Schilde for their excellent technical assistance and field work. We are grateful for the major support provided by the Division of Theoretical Bioinformatics, and the Heidelberg Center for Personalized Oncology, DKFZ-HIPO of the German Cancer Research Center (DKFZ) in Heidelberg, Germany.

Author contribution

IL, RE, MKa, and ST provided project leadership.

AvB, BS, JH, MB, SR, EvM, JR, ADC, RL, MKa, AMK, IL, GH were involved in the recruitment and field work of the cohorts.

GH provided cytokine data.

MB provided the RNA transcription data.

SDM, MK, MB, TB, and CH performed the DMR calling and DMR annotation.

MK, LT, DW, OM, and CP performed or guided targeted methylation analyses.

MK, SDM, MM, MB, NI, TB, CH, ST, GS, and LT performed or supervised data analysis.

SS, EF, UH, MK and ST performed or evaluated NLP analysis.

LT, ST, MK, and IL wrote the manuscript.

All authors were involved in the discussion and contributed to the final manuscript.

Figure 1: Study design. Blood samples derived from asthmatics or control children of the three cohorts were subjected to WGBS to determine asthma-related DMRs. DMRs comparing asthmatic and control children were determined by the two independent DMR-calling algorithms DSS and metilene. Asthma-related DMRs were subsequently analysed.

DMR = differentially methylated region, WGBS = whole-genome bisulfite sequencing, LINA = lifestyle and environmental factors and their influence on newborns allergy risk, LISA = influences of lifestyle-related factors on the immune system and the development of allergies in childhood, PASTURE = Protection Against Allergy: Study in Rural Environments

[2] based on available whole blood samples of LINA and LISA

[3] based on available plasma samples of LINA

Figure 2: DMR distribution and down-stream analyses. (A) Circos plot represents the distribution of the 158 differentially methylated regions (DMRs) identified in asthmatic children vs. controls across all autosomes. The outer circle shows the 22 autosomes. The bars in the inner circle represent the DMRs and their chromosomal location. Hypermethylated DMRs are indicated as red bars, hypomethylated DMRs in blue. The height of each bar indicates the DNA-methylation differences between asthmatics and controls. **(B)** KEGG pathway enrichment for all asthma-DMRs based on their genomic location. **(C)** DNA-methylation difference between asthmatic children and controls of the WGBS samples (asthma n=40, controls n=42), LINA study (asthma n=19, controls n=108) and LISA study (asthma n=25, controls n=115) for DMRs related to *EPX* and *IL5RA* as determined by sequencing or MassARRAY, respectively (*p*-value from Mann-Whitney U-test, r_{pb}:

point biserial correlation coefficient). **(D)** Association of *EPX* and *IL5RA* DNA-methylation (black whiskers) and transcription (magenta whiskers) to asthma outcome in meta-analysis combining LINA and the LISA study (DNA-methylation: asthma n=44, controls n=223, *EPX* transcription: asthma n=44, controls n=220, *IL5RA* transcription: n=44 asthma n=222 controls). Given are ORs with +/-95% CIs from logistic regression adjusted for child's sex, cohort, prenatal tobacco smoke exposure, family history of atopy, parental school education and maternal age at birth using ln-transformed DNA-methylation values.

Figure 3: Genomic location of asthma-related DMRs and functional translation of *IL4* enhancer hypomethylation. (A) Pie chart represents the proportional distribution of the genomic regions affected by asthma-related DMRs. **(B)** Genomic location of the *IL4* DMR and the genomic region analysed by MassARRAY in the UCSC genome browser[64]. **(C)** Scatterplots show the association of *IL4* DNA-methylation to *IL4* transcription (n=112) and IL-4 protein concentration (n=115) and the association of IL-4 protein concentration to *IL4* transcription (n=111) in six-years-old children of the LINA study. Correlation coefficient (ρ) and p-value from Spearman correlation. **(D)** Mediation analysis for the relationship of *IL4* enhancer DNA-methylation, *IL4* transcription, and IL-4 protein concentration of six-years-old children of LINA (n=111). Model was adjusted for child's sex, prenatal tobacco smoke exposure, family history of atopy, parental school education and maternal age at birth. IL-4 protein concentrations were determined after PHA-stimulation. Protein and DNA-methylation data were ln-transformed before analysis. Effect sizes for indirect path is given as standardized β-values with +/-95% CIs. Significance determined by bias-corrected bootstrapping.

MA = MassARRAY, DMR = differentially methylated region

Figure 4: Network module analysis of asthma-DMR associated genes. Shown are all asthma-DMR associated genes, which show a predicted or experimentally based interaction. Only modules with more than one connection are shown. Target genes of enhancers affected by a DMR are highlighted by blue outline circles. Genes related to asthma or similar terms as determined by the natural language processing tool are indicated in red font. Module nomenclature is based on subsequent pathway enrichment analysis (Table S12).

Figure 5: Cord blood asthma-DMRs. (A) Matched cord blood samples were subjected to WGBS to determine the DNA-methylation level of the asthma-related DMRs at time of birth in control children compared to those children who later developed asthma. **(B)** Pie charts represent the portion of genotype-, and non-genotype-associated DMRs (g/ngDMRs) and those DMRs, which were already differentially methylated in cord blood samples (=cord blood DMRs). The table lists all prenatal influencing factors that have previously been associated with CpGs included in the n=56 cord blood asthma-related DMRs (see Table S6C for EWAS references and cord blood DMR list). Genes highlighted in red font were described with asthma as identified by natural language processing (see Table S13B for references). #ngDMRs indicated with light blue and gDMR with dark blue background. *Enhancer target genes were derived from GeneHancer, in cases where no GeneHancer annotation was available the closest TSS gene is given. **(C)** Network module analysis for cord blood DMR associated genes (left panel) and for genes associated to DMRs only present in asthma phenotype (right panel). Only modules with more than one connection are shown. Module nomenclature is based on network of Figure 4.

PFOS = perfluorooctane sulfonic acid, NLP = natural language processing

Figure S1: Literature search for overlap of DMRs with previous EWAS. (A) Workflow summarizes the EWAS studies investigated asthma-related outcomes, which were used for the overlap with n=158 asthma-related DMRs. **(B)** Workflow summarizes the EWAS studies investigated prenatal influencing factors, which were used for the overlap with n=56 cord blood asthma-related DMRs.

Figure S2: Quality control of the MassARRAY amplicons. Graphs show DNA-methylation values derived by MassARRAY measurements of standard samples (0%, 20%, 40%, 60%, 80%, and 100% methylated genomic DNA) representing the mean DNA-methylation of the MassARRAY amplicon for **(A)** *IL5RA* (including 7 CpGs), **(B)** *EPX* (including 9 CpGs) and **(C)** *IL4* (including 6 CpGs) DMR (given are mean ±SD of two replicates and r^2 from linear regression).

Figure S3: Study workflow. DMRs comparing asthmatics and control children of three cohorts were called by two independent algorithms (DSS, metilene) and concordant DMRs were subjected to multiple test corrected factorial ANOVA analysis to determine asthma-related DMRs. These 158 DMRs were subsequently analysed and categorized based on their dependency on the genotype, the cell type composition or their presence also in cord blood.

DMR = differentially methylated region, ng/gDMR = non-genotype/genotype-associated DMRs

Figure S4: Characteristics of asthma-related DMRs. (A) Cluster analysis with ß-methylation values of the 158 asthma-related DMRs. **(B)** CoMET plot of the validated *EPX* and *IL5RA* DMR. Plots show WGBS derived β-methylation values of asthmatics vs. control children on top (n=40 vs. 42, mean +/-SEM) followed by *p*-values from logistic regression analysis (asthma phenotype ~

β-values) and UCSC tracks (ENSEMBL genes, CpG islands, DNAse-sensitive regions and SNPs) as well as the DNA-methylation correlation matrix for all CpG sites within the DMRs.

Figure S5: Epigenetic regulation of *IL5RA* and *EPX* transcription in asthma. (A) Correlation between *IL5RA* and *EPX* DNA-methylation to *IL5RA*/*EPX* transcription of children of the LINA (magenta) and LISA (black) study. Correlation coefficient ρ and *p*-value from Spearman correlation. **(B)** Relative gene expression of *IL5RA* and *EPX* in asthmatic children and controls participated in LINA (asthma n=19, controls n=107) or LISA (*IL5RA*: asthma n=25, controls n=115, *EPX:* asthma n=25, controls n=113). *p*-value from Mann-Whitney U-test, r_{pb}: point biserial correlation coefficient.

Figure S6: IL-4 protein and *IL4* enhancer hypomethylation in asthma. Illustrated is the mediation model adjusted for child's sex, prenatal tobacco smoke exposure, family history of atopy, parental school education and maternal age at birth. Effect sizes for the indirect path is given as standardized *β*-values with +/-95% bias-corrected bootstrap CIs (n=111, significant as determined by bootstrap CI). The analysis is shown for the LINA subcohort with available PHA-stimulated IL-4 protein concentrations. Protein and DNA-methylation data were ln-transformed before analysis.

Global hypomethylation in childhood asthma identified by genome-wide DNA-methylation sequencing preferentially affects enhancer regions

ABSTRACT

Background: Childhood asthma is a result of a complex interaction of genetic and environmental components causing epigenetic and immune dysregulation, airway inflammation and impaired lung function. Although different microarray based EWAS studies have been conducted, the impact of epigenetic regulation in asthma development is still widely unknown. We have therefore applied unbiased whole genome bisulfite sequencing (WGBS) to characterize global DNA-methylation profiles of asthmatic children compared to healthy controls.

Methods: Peripheral blood samples of 40 asthmatic and 42 control children aged 5-15 years from three birth cohorts were sequenced together with paired cord blood samples. Identified differentially methylated regions (DMRs) were categorized in genotype-associated, cell-type-dependent, or prenatally-primed. Network analysis and subsequent natural language processing of DMR-associated genes was complemented by targeted analysis of functional translation of epigenetic regulation on the transcriptional and protein level.

Results: In total, 158 DMRs were identified in asthmatic children compared to controls of which 37% were related to the eosinophil content. A global hypomethylation was identified affecting predominantly enhancer regions and regulating key immune genes such as *IL4, IL5RA*, and *EPX*. These DMRs were confirmed in n=267 samples and could be linked to aberrant gene expression. Out of the 158 DMRs identified in the established phenotype, 56 were perturbed already at birth and linked, at least in part, to prenatal influences such as tobacco smoke exposure or phthalate exposure.

Conclusion: This is the first epigenetic study based on whole genome sequencing to identify marked dysregulation of enhancer regions as a hallmark of childhood asthma.

Key words:

asthma, cord blood, DNA-methylation, prenatal exposure

INTRODUCTION

Asthma is the most common chronic inflammatory disease in childhood. With an estimated prevalence of asthma ranging from 2.6% to 30.5%[1] varying according to the age and origin of the children, childhood asthma is a major health concern worldwide. Over the last decades, the prevalence of childhood asthma increased in a majority of countries worldwide, which has been mainly attributed to an interaction of genetic predisposition with a changing environment and a Westernized lifestyle[1,2]. Although the etiology of pediatric asthma remains incompletely understood, its origin is thought to be found early in life[3]. There is a larger number of studies supporting the notion that asthma-related immune alterations are already established during the prenatal development phase when the maturation of the immune system begins[4]. Although the molecular mechanisms initiating and maintaining these aberrant immune functions are largely unknown, epigenetic mechanisms are thought to play a central role in not only mediating the adverse effects of an intrauterine environment but also in preserving the established asthma-promoting phenotype[4]. However, the knowledge of asthma-related epigenetic modifications is limited and no genome-wide studies at a single base-pair resolution are available. So far, DNA-methylation changes in asthma, have been described based on target-specific analyses or on DNA-methylation microarrays[5-9] covering 27,000-850,000 CpG sites of the approximately 28 million CpGs of the human genome.

To date, several childhood asthma-associated DNA-methylation changes at single CpG sites located in immune regulatory genes such as *ALOX12*, *IL13*, and *RUNX3*, or genes involved in arachidonic acid metabolism, T cell differentiation, and IgE production, have been described in whole blood samples[7,10]. In addition, more than 100 differentially methylated sites were identified by array-based epigenome-wide association studies (EWAS) on respiratory cells, such as buccal cells or epithelial cells of the nasopharynx, amongst others CpGs in the close vicinity of established asthma-associated genes, such as *ZFPM1*, *NLRP3*, *IFNGR2*, *NTRK1*, or

ALOX15[11-13]. However, all of the current EWAS on asthma are biased by the pre-selection of CpG sites covered by the commercially available DNA-methylation arrays.

The genomic localization of DNA-methylation changes is critical for their functional impact on gene expression and associated relevance to the disease phenotype. Perturbations in regulatory regions, and in particular enhancers regulating multiple genes, are assumed to drive disease progression[14]. Enhancers are not commonly in close vicinity of their target gene, but rather may be located several thousands of base pairs away[15]. Although previous studies of asthma-associated DNA-methylation changes provided valuable information on CpG sites potentially contributing to disease etiology and suggested an enhancer-centric epigenetic dysregulation[9], a plethora of enhancer elements have since been identified that are not covered by DNA-methylation arrays and thus have previously escaped analysis. Even with the advanced EPIC array only 7% of distal and 27% of proximal ENCODE regulatory elements, and less than 4% of all CpGs of the genome are represented[16].

As a consequence of this limited genomic coverage of previous methylation array studies only little is known about enhancer dysregulation in childhood asthma. To overcome this knowledge gap, this study used a different approach and determined the unbiased global DNA-methylation profile at a single-base pair resolution by applying whole-genome bisulfite sequencing (WGBS). Whole blood samples of 40 asthmatic children from three independent prospective birth cohorts were compared to 42 sex- and age-matched controls. It is well known that the methylation of adjacent CpG sites is mutually dependent[17] and regional changes in DNA-methylation are assumed to be functionally more relevant than single CpG positions[18]. Thus, we determined differentially methylated regions (DMRs) rather than reporting methylation changes at single CpG positions and subsequently confirmed our findings by targeted methylation analyses in larger number of cases that included subjects from two of the three cohorts. The comprehensive assessment of the genomic distribution of the DMRs was complemented by elucidating the functional consequences of aberrant DNA-methylation

associated with key immune modulating genes. To this end, cord blood - available for a subset of the children - provided the opportunity to assess potential prenatal priming of the DNA-methylation changes identified in asthmatic children.

METHODS

Detailed information can be found in the Online Supplement.

Study characteristics

This study comprises data and samples derived from the three different birth cohorts LINA[19], LISA[20], and PASTURE[21]. A detailed cohort description can be found in the Online Supplement. Participation in all three cohort studies was voluntary and written informed consent was given by the parents or children if applicable. The studies were approved by their respective ethics committees (LINA: 046-2006, 160-2008, 160b/2008, EK-BR-02/13-1, 169/13ff, 150/14ff, LISA: 398-12-05112012, PASTURE: 02046, 9/11-E1/651-2002, 415-E401/4-2007).

Asthma outcome

Asthma was defined based on the confirmative answer to the question: "Has a physician-diagnosed your child with asthma during the last 12 months (=current asthma)?" asked in the parent-reported questionnaires at the time-point when blood samples were obtained for DNA-methylation analysis.

Sample selection

From each of the three cohorts, cases and controls were randomly selected to derive a balanced selection of children diagnosed with asthma and of age- and sex-matched controls. As a prerequisite a sufficient quantitative and qualitative amount of genomic DNA had to be available. For the asthma group only children with a physician-made asthma diagnosis at the time of WGBS analysis were selected. For the control group, children were chosen who never reported wheezing symptoms, obstructive bronchitis, asthma, rhinitis or atopic dermatitis. A total of 40 children aged five to 15 years of age with a current asthma diagnosis and 42 age-

and sex-matched controls were selected for WGBS analysis. An overview of the selected samples is provided in Table S1.

For 48 children investigated at the time of an established asthma phenotype paired cord blood DNA samples were available (n=23 asthma, n=25 controls; Table S1) and also subjected to whole genome bisulfite sequencing.

Whole-genome bisulfite sequencing (WGBS)

To assess quantitative DNA-methylation information at single base pair resolution, whole blood genomic DNA samples from 82 children of the three cohorts and 48 matched cord blood samples available from LINA and PASTURE (Table S1, Table S2) were subjected to WGBS (see Online Supplement for details) as previously described[22]. All samples showed bisulfite conversion rates >99%.

Pre-processing of WBGS data

Sequencing data for each sample was input to the one touch pipeline[23] and processed using bwa v0.6.1.[24] and methylCtools v1.0.0[25] resulting in tab separated output files containing CpG position, number of reads with a methylated cytosine at this position, total number of reads covering the CpG and a *snp score*[26], which is the estimated probability of the CpG to be a SNP. CpGs were removed from the whole cohort if at least one of the 82 samples had a *snp score* of 0.25 or greater.

Determination of asthma-associated DMRs

Asthma-related DMRs were determined by a three-step procedure (i-iii). (i) DMRs were defined as at least three consecutive differentially methylated CpG sites between asthmatics (n=40) and controls (n=42). DMRs were called by two independent algorithms, a DMR calling strategy, which was applied in the latest meta-analysis on childhood asthma using 450k array data[8]. For

our WGBS data we used DSS version v2.12.0[27], and metilene version v0.2-6[28] as DMR calling tools. For DSS we used a Wald-test *p*-value threshold of .01 to mark a CpG as differentially methylated. The minimum DMR length was set to 50 bp, the maximum distance between two CpGs was set to 100 bp and the fraction of differentially methylated CpGs was set to minimum 0.3. Metilene uses circular binary segmentation followed by two dimensional Kolmogorov–Smirnov test (2D-KS test) and a DMR was considered significant if the obtained *q*-value was less than 0.05. Only chromosomes 1-22 were included in the analysis, while sex chromosomes were omitted. DSS adopts a highly appropriate beta binomial model for modelling DNA-methylation from WGBS count data but does not provide significance testing nor multiple testing correction of the identified DMRs. On the other hand, metilene offers the ability to perform multiple testing correction for the identified DMRs. Given the different approaches and features adopted by these two tools, we deemed their overlap to be highly conservative, thereby reducing potential false positives. (ii) To reduce the likelihood of false-positive DMR calls, we kept only the metilene DMRs that overlapped at least by 1 bp with the DMRs from DSS. The overlap was determined by using *intersectBed* from Bedtools version 2.24.0[29]. (iii) Concordant DMRs were tested for significance in each of the three cohorts LINA, LISA, and PASTURE by a factorial ANOVA using R version 4.0.2[30]. Log transformed β-values with a pseudo count of 0.006 of all differentially methylated CpGs within a DMR were modelled by using the disease condition asthma/control and the CpG position within a DMR. If the Bonferroni adjusted *p*-values in each of the three cohorts were $p<.05$ then a DMR was considered as significantly differentially methylated and retained for further analysis.

Overlap with previous asthma-associated EWAS

Previous asthma-associated EWAS studies in the PubMed database were identified by the search term: ("asthma" OR "wheeze") AND ("WGBS" OR "EWAS" OR "450k" OR "850k" OR "27k" OR "epigenome-wide" OR "HumanMethylation450K BeadChip") AND "blood"

(query data 27.10.2022). This search retrieved 68 publications, from which two reviews, one RCT and one systematic review were excluded. After manual curation 22 EWAS studies (including meta-analyses) remained that reported DNA-methylation changes in blood related to asthma or lung function (Figure S1A). DNA-methylation changes described in these manuscripts were related to the DMRs observed in our study.

Gene annotation and definition of enhancer and promoter DMRs

Genomic annotation of DMRs to the nearest transcription start site (TSS) from Gencode v19 gene models in human genome version hg19 was obtained by using the 'closest' module from Bedtools. Promoter regions were defined as 2 kb up- and downstream of the TSS. DMRs overlapping with at least 1 bp were categorized as promoter DMRs. DMRs were defined as enhancer DMRs, if their genomic location intersected at least 1 bp with GeneHancer[31], ENCODE[32], or ROADMAP[33] enhancer regions, or with an active histone mark as previously identified in LINA children according to Bauer *et al.*[22] (Table S3). Predicted target genes of enhancer DMRs were identified by using GeneHancer.

DMR classification

All asthma-related DMRs were classified into different categories: (i) genotype-/non-genotype-associated, (ii) cell-type-dependent, (iii) already present in cord blood. Asthma-related DMRs already present in cord blood were overlapped with previous EWAS studies investigating prenatal factors that affect DNA-methylation (see Online Supplement for details and Figure S1B).

According to previous works[19,22], a DMR was categorized as genotype-associated (gDMR) whenever a significant correlation between the methylation value of the DMR and any SNP in a +/-5 kb window around the DMR was determined (see Online Supplement for details). Likewise, DMRs with no significant association to methylation quantitative trait loci (meQTLs)

were classified as a non-genotype associated DMR (ngDMR). All meQTL SNPs were checked against the EMBL GWAS catalogue[34] (Query date: 01.11.2022) for previous associations to any phenotypic outcomes including asthma.

To determine whether the asthma-related DMRs were already differentially methylated at the time of birth, WGBS-based DNA-methylation data of matched cord blood samples were analysed (n=48, Table S1, Table S2). Whenever a DMR was significantly differentially methylated at the time of birth as determined by factorial ANOVA followed by a multiple test correction (Bonferroni-corrected $p<.05$, corresponding to a nominal $p<.00032$ separately in all three cohorts), the corresponding DMR was classified as a cord blood asthma-DMR already present at the time of birth.

To identify which cord blood DMRs were associated with a prenatal influencing factor, previously published array- or WGBS-based EWAS conducted with cord blood samples were evaluated (see Figure S1B and Online Supplement for details). This included studies on maternal smoking during pregnancy, maternal mental health, maternal disease such as diabetes and atopy, maternal BMI and diet, or environmental exposures. Whenever a CpG or region previously associated with a prenatal influencing factor overlapped with at least 1 bp with a cord blood DMR in our data set, this DMR was considered to be associated with this prenatal influencing factor.

Cell-type dependency

The frequency of the main blood cell types (T cells, B cells, NK cells, monocytes, neutrophils, eosinophils) was estimated by deconvolution of the WGBS data using *EpiDish*[35].

Next, the cell-type dependency of DMRs was determined using adjusted multiple regression models with the mean DNA-methylation of the DMR as the dependent variable and the main blood cell-type estimates as the independent variables (confounder: child's sex, cohort, prenatal tobacco smoke exposure, family history of atopy, parental school education, maternal age at

birth, growing up on a farm). DMRs significantly (Bonferroni-corrected $p<.05$, corresponding to a nominal $p<.00032$) associated to a specific blood cell type were classified as cell-type-dependent (see Online Supplement for details).

Enhancer-, pathway- and TFBS motif enrichment

We used Fisher's exact test in R to test if asthma-related DMRs were enriched for enhancer elements (Table S3) when comparing them with all other methylated regions in the genome that have similar characteristics as our DMRs but are not called as such (see Online Supplement for details).

For gene enrichment analysis the genomic positions of asthma-related DMRs were subjected to GREAT (Genomic Regions Enrichment of Annotations Tool) version 3.3.0 analysis tool[36] setting "whole genome" as background and a significance level of $\alpha<.05$.

The MEME-ChIP tool implemented in the MEME Suite version 5.4.1 (Motif-based sequence analysis tools)[37] was used to identify transcription factor binding site (TFBS) based on the HOCOMOCOv11 core HUMAN database including *de novo* motifs within the asthma-related DMRs. DMRs were elongated by 20 bp at the start and at the end to ensure an intersection with motif sequences. Only motifs with a length of four to fifteen nucleotides were considered. Motif enrichment with an *E*-value<.05 (estimate of the statistical significance of each motif) was considered significant.

Network analysis and Natural Language Processing

For network and module analysis of DMR associated genes including all enhancer DMR target genes or genes closest to the next TSS (n=435 genes) were subjected to Cytoscape analysis version 3.8.2[38]. The Reactome Functional Interaction (FI) plugin version 8.0.4 (released Feb 2022) was used to determine network patterns of common and predicted interactions as estimated via Naïve Bayes Classifier excluding linker genes. Cluster FI network was applied to

identify cluster of genes (=modules)[39]. Subsequently, a pathway enrichment analysis (significance cut-off: FDR<0.01) was performed using the databases CellMap, Reactome, KEGG, NCI PID, Panther and BioCarta for each module.

To identify genes in the network, previously associated with asthma-related outcomes, natural language processing (NLP, see Online Supplement for details) was applied. In brief, mentions of genes and gene products were searched in the PubMed and PubMed Central open access literature databases and additionally filtered by the following terms “asthma”, “asthmatic”, “asthmatics”, “wheeze”, “bronchial hyperreactivity”, “airway hyperreactivity”, “bronchial hyperresponsiveness”, or “hyperreactive airway disease”.

Targeted analyses: DNA-methylation, transcription, and protein measurement

Targeted analyses were performed in a larger sample set obtained from the 6-8 years old LINA children and the 15-years old LISA children from the Leipzig study centre. No further PASTURE samples were available for these analyses. All available samples from LINA and LISA fulfilling these two criteria were included: (i) samples from children diagnosed with asthma by a physician and (ii) control samples that never reported wheezing symptoms, obstructive bronchitis, or asthma, however they could have developed atopic dermatitis or rhinitis. An overview of the selected samples for these analyses is provided in Table S1 and Table 1B.

Targeted DNA-methylation analysis was performed for a set of selected DMRs in n=127 LINA and n=140 LISA samples using the Sequenom´s MassARRAY platform (San Diego, CA, USA, Table S4 for primer sequences, Figure S2) as previously described[22].

Functional translation of methylation changes for selected genomic regions was determined by RNA and protein expression analyses of the associated genes. Whole blood samples for transcriptional analyses were collected at the same time as blood samples for DNA-methylation analyses. RNA expression data were obtained for *EPX*, *IL4,* and *IL5RA* for n=126 LINA and

n=140 LISA samples by qPCR on the Biomark HD system as previously described[22] (see Table S5 for primer sequences).

Within the LINA study phytohaemagglutinin (PHA)-stimulated IL-4 concentrations obtained from a whole blood assay were available. IL-4 concentrations were measured by cytometric bead array (BD CBA Human Soluble Flex Set system, Becton Dickinson, Heidelberg, Germany) as previously described[40].

Detailed information can be found in the Online Supplement.

Statistics

WGBS samples

To determine potential differences in the study characteristics between asthmatic and control children a Fisher's exact- test or Mann-Whitney *U*-test were applied. As confounding factors in the models analysing WGBS-data the child's sex, cohort, prenatal tobacco smoke exposure, family history of atopy, parental school education, maternal age at birth, growing up on a farm and cell composition were included.

Targeted analyses

To test whether there were differences between asthmatic and control children of the LINA and LISA cohorts with respect to the child's age and sex, prenatal tobacco smoke exposure, family history of atopy, parental school education, maternal age at birth, growing up on a farm, or the presence of rhinitis or atopic dermatitis in the child, Fisher's exact- test or Mann-Whitney-*U* test were applied.

A Mann-Whitney-*U* test was used to determine if there were significant differences in DNA-methylation and transcription between groups. Spearman correlation was used to determine the association between DNA-methylation, relative gene expression, or protein concentration. Correlation coefficients are reported as effect size measures (point biserial (r_{pb}) for Mann-

Whitney U and Spearman's rho ρ). The selection of confounders associated with asthma or affecting DNA-methylation patterns was based on *a priori* knowledge. The child's sex, cohort, prenatal tobacco smoke exposure, family history of atopy, parental school education and maternal age at birth were introduced as confounding factors in all models.

Confounder adjusted logistic regression analyses were applied to compare the DNA-methylation and relative gene expression of asthmatic and control children. Confounder adjusted mediation analyses were performed using the *PROCESS* macro version v3.4[41] for SPSS. Statistical significance of the indirect effect was determined by bootstrapping as implemented in the *PROCESS* macro version 3.4[41]. Bias-corrected 95% confidence intervals were derived from the distribution of bootstrap estimates of the indirect effect from random resampling of 5,000 samples. Only for non-dichotomous independent variables a standardized indirect effect was calculated. Effect sizes of regression analyses are either provided as unstandardized *b*, standardized β, or as odds ratio (OR).

Statistical analyses were performed using STATISTICA for Windows Version 12.0/13.0 (Statsoft Inc. Europe, Hamburg, Germany), IBM SPSS Statistics for Windows Version 25 (IBM Corp. Released 2013. IBM SPSS Statistics for Windows, Version 22.0. Armonk, NY: IBM Corp.) or R version 4.0.2[30]. *P*-values $\leq .05$ were considered significant.

RESULTS

Genome-wide DNA-hypomethylation in childhood asthma

To evaluate epigenetic alteration in the global DNA-methylation pattern of asthmatic children at single base-pair-resolution, we performed WGBS and subsequent DMR calling of whole blood samples from n=82 children participating in the LINA, LISA, or PASTURE cohort (Figure 1, Table S1). In total, samples from n=40 asthmatic children were compared to n=42 age-matched controls without an asthma history or other respiratory symptoms (Table 1A). High quality WGBS data were derived with a mean genome coverage of 56.3x (Table S2A). To retain highly confident asthma-related DMRs for downstream analyses, a multiple-step DMR-calling approach was utilized (Figure S3). Using these two independent DMR-calling algorithms, DSS and metilene, 1,021 and 758 DMRs were determined, respectively. DMRs overlapping between these two approaches (n=385) were subjected to factorial ANOVA analysis to assess whether significant DNA-methylation differences could be observed separately in each of the three cohorts and were in the same direction. Only these concordant DMRs (n=158 out of n=385) were retained for further assessment (Figure S3, see Table S6A for asthma-related DMR list). These 158 asthma-related DMRs were distributed over all autosomes (Figure 2A) and had a read coverage of 31.5x in average (Table S2B). Unsupervised cluster analysis of these derived 158 DMRs resulted in a clear separation between asthmatics and control children (Figure S4A). The vast majority of the asthma-related DMRs were hypomethylated in asthmatic children (Figure 2A), while only two hypermethylated DMRs located in the *TET3 (ten-eleven translocation 3 or tet methylcytosine dioxygenase 3)* gene and the long coding RNA *AL645608.1* were identified. In line with previous asthma EWAS studies our DMRs overlapped with several CpG sites or DMRs identified based on array approaches (see Table S7 for overlap and references and Figure S1A for evaluated EWAS studies).

Genetic and cell type composition influences on asthma-related DMRs

Since the level of DNA-methylation can be strongly dependent on the genotype or the cell type composition, asthma-related DMRs were categorized according to cell type-dependency and genotype-association (gDMRs). Based on this categorization, 38 out of the 158 DMRs were associated with the genetic background (24.1%), while the remaining 120 DMRs (75.9%) were classified as non-genotype associated DMRs (ngDMRs). A total of 465 meQTLs were identified in relation to the 38 gDMRs, of which none has been previously described as an asthma risk factor in genome-wide association studies (Table S6B). However, including all phenotypic traits of the GWAS catalogue, we found 14 DMRs associated with at least one trait. For eight of these DMRs, the trait showed a loose phenotypic association with asthma (Table S6B) including lung function (rs645601 and rs7700998). Five SNPs were associated to counts of different blood cell types with SNPs rs4328821 and rs7646596 upstream of the *RPN1*-DMR associating to the eosinophil count. Additionally, rs12699415 related to the *MAD1L1*-DMR was linked to idiopathic pulmonary fibrosis[34].

We observed an enhanced eosinophil frequency in the blood of asthmatic children (Mann-Whitney *U* test: Z=3.42, r_{pb}=0.32, p= .017, Table S8), but not for the remaining cell types, i.e. B cells, T cells, monocytes, NK cells or neutrophils. We applied adjusted multiple regression analyses to test whether different cell type frequencies have an impact on the DNA-methylation level of the determined DMRs. To this end, 37% of the asthma-DMRs (58 DMRs) were associated with the eosinophil proportion and only three DMRs in total to B cells, T cells, monocytes, NK cells or neutrophils (Table S6A). However, even after accounting for these cell types in the adjusted multiple regression models, asthma was still a significant contributor of the DNA-methylation status for all cell-type-dependent DMRs (Table S9).

Altered DNA-methylation pattern associates with perturbed immune regulation

To elucidate the relevance of the asthma-related aberrant DNA-methylation profile, a pathway enrichment analysis was performed. Besides a strong enrichment in the asthma pathway, we

found classical immune system-related pathways enriched, such as IL-5- known to be crucial for asthma pathophysiology[42,43] (Figure 2B, Table S10). To ensure that the DNA-methylation differences observed in the small number of sequenced samples can be reproduced in larger sample numbers, targeted analyses were performed in further samples (n=267) including six to eight-years-old LINA children (n=127) and 15-years-old LISA adolescents (n=140, Table S1, Table 1B). Here, we focused on DMRs that are likely to influence aberrant immune gene expression driving asthma onset. Therefore, the DNA-methylation of two prototypical DMRs (Figure S4B) linked to genes of the asthma pathway (eosinophil peroxidase, *EPX*) - the pathway with the strongest enrichment - and the IL-5 signalling pathway (*IL5RA*) (Figure 2B) known to promote severe atopic asthma associated with eosinophilia[42], was measured in the larger sample set using a targeted DNA-methylation assay. Significant hypomethylation of these DMRs located in the sixth exon of *EPX*, and in the *IL5RA* promoter, could be confirmed in meta-analysis combining samples of the LINA and LISA cohort (adj. OR/95% CI *EPX*: 0.87/0.81-0.94, p=.0004; *IL5RA:* 0.83/0.73-0.94, p=.003, n=223 controls vs. n=44 asthmatics, Figure 2C,D) using logistic regression adjusted for the child's sex, cohort, prenatal tobacco smoke exposure, family history of atopy, parental school education and maternal age at birth. Furthermore, for both DMRs a negative correlation with the relative gene expression of the associated genes *EPX* was observed (ρ= -0.40, p=1.4x10^{-11}, n=264) and *IL5RA* (ρ= -0.32, p=1.4x10^{-7}, n=266, Figure S5A). In line, expression of *EPX* and *IL5RA* is not only increased in asthmatic children (Figure S5B) but is also associated with an increased risk for asthma during childhood (relative expression *EPX*: adj. OR/95% CI: 1.44/1.09-1.91, p=.010, n=220 controls vs. n=44 asthmatics, *IL5RA:* adj. OR/95% CI: 1.59/1.19-2.13, p=.002, n=222 controls vs. n=44 asthmatics, Figure 2D).

DNA-methylation changes in asthma affect regulatory hubs

The identified DMRs showed enrichment for 20 binding motifs related to different transcription factors previously associated with asthma including the Th2 master regulator GATA3[44] (Table S11). Additionally, two third of the DMRs were located in genomic regulatory elements, 74% of the DMRs intersecting with enhancers, and 1% with promoters (Figure 3A). In particular, the DMR enrichment in enhancer regions was highly significant (OR/95% CI: 5.83/4.05-8.53, $p<4.0x10^{-26}$). Among the DMRs overlapping with a ROADMAP enhancer active in specific blood cells (Table S3), 17 DMRs overlapped with a T helper cell-type specific enhancer including a hypomethylated enhancer DMR associated with the mTORC1 scaffolding protein coding gene *RPTOR* (Table S6A).

One of those hypomethylated enhancer regions showed an enhancer specific ENCODE histone modification profile and a ChiA-PET interaction to the *IL4* promoter (Figure 3B). Although IL4 is one of the key regulators in allergic diseases including asthma, the relevance of this particular enhancer region associated to IL-4 expression has not been addressed so far. We confirmed the asthma-related DNA-hypomethylation of this *IL4* enhancer in the meta-analysis combining the two cohorts LINA and LISA (adj.OR/95% CI: 0.83/0.74-0.94, p=.002, n=223 controls vs. n=44 asthmatics). In addition, in the LINA cohort, where IL-4 protein concentration measurements were available (Table S1), the *IL4* enhancer DNA-methylation was associated with *IL4* transcription (ρ= -.35, p=.0001) and PHA-stimulated IL-4 protein concentrations (ρ= -.31, p=0.0009, Figure 3C). In line, two confounder adjusted mediation models were applied to evaluate the relevance of this hypomethylated *IL4* enhancer region in asthma: The first model showed a significant indirect effect of *IL4* enhancer DNA-methylation on IL-4 protein concentration via *IL4* transcription as a mediator (β/95% CI: -0.07/ -0.14- -0.03, Figure 3D), whereas the direct effect was not significant (b/95% CI: -0.92/ -3.79- 1.95, p= .525). Second, the asthma phenotype contributed to an increase in IL-4 protein concentration in asthmatics again solely indirectly via the DNA-methylation changes of this *IL4* enhancer and *IL4*

transcription as mediators (Figure S6, indirect effect: *b*/95% CI: 0.05/ 0.01- 0.13; direct effect *b*/95% CI: 0.23/ -0.26- 0.73, *p*=.352).

Genes affected by DNA-methylation changes are functionally connected

To elucidate whether DMR associated genes (n=435 genes, Table S6A) were functionally connected, these genes were subjected to network analysis based on established protein-protein interactions with a subsequent pathway enrichment of the derived network modules. The resulting network consisted of 102 genes in thirteen distinct modules. These modules were related, among others, to immune response and inflammation, cilium assembly and general gene regulation, and to Jak-STAT signalling (Figure 4, Table S12). The vast majority of the network genes (97 out of 102 genes) were targets of differentially methylated enhancers. Our NLP analysis revealed that 33.3% of these enhancer target genes such as the central transcription factors of the immune system *RELA* (NFκB subunit encoding gene)*, GATA2,* and *ZFPM1,* the Th2 cytokine *IL4,* or the mTOR complex 1 scaffold protein *RPTOR* have previously been described in the literature in association with asthma (red genes in Figure 4, Table S13A). In addition, we identified novel genes not yet associated to asthma, such as the A-kinase anchoring protein-9 (*AKAP9*). *ANKAP9* is prominently expressed in T cells and involved in immune synapse formation[45]. Among the proteins interacting with ANKAP9 for its proper function are TUBGCP2/TUBGCP6, for which we also observed an enhancer DMR[46].

Prenatal priming for asthma

To discriminate between DMRs that are a consequence of the disease from those predisposing an individual, we subjected matched cord blood samples (n=23 asthmatics vs. n=25 controls) to WGBS and assessed whether the methylation changes of the 158 asthma-related DMRs were already present at time of birth (Figure 5A). 35% (56/158 DMRs) of the DMRs identified in the established asthma phenotype were already significantly differentially methylated in cord blood

samples (Table S6C). Most of the cord blood DMRs were again located in enhancers (43 out of 56), 39% (n=22/56 DMRs) were gDMRs including those already identified in GWAS as a risk factor for lung dysfunction and idiopathic pulmonary fibrosis[34] (Table S6C). For 22 out of the 56 cord blood DMRs, we found an overlap with previous EWAS studies investigating the impact of a variety of different prenatal factors on DNA-methylation (Figure S1B). These factors included exposure to tobacco smoke, to air pollution or to environmental chemicals such as phthalates or lead, maternal diet-related metabolites as well as factors related to maternal health like gestational diabetes or preeclampsia (Figure 5B, Table 13B). When focusing our network analysis on cord blood DMR associated genes the network was comprised of several members of the LFA-1 signaling pathway (Figure 5C). Next to *ITGAL* coding for one of the subunits of LFA-1 (=CD11a), also the LFA-1 ligand ICAM-1, and the co-chaperones *ANKAP9*, *TUBGC2/6* were among the target genes of DMRs already observed in cord blood.

DISCUSSION

To characterize the complete genome-wide DNA-methylation pattern in childhood asthma, this study determined the DNA-methylation profile of 40 asthmatic and 42 control children by utilizing WGBS followed by calling of differentially methylated regions (DMRs) and discriminating between genotype-, and non-genotype-associated as well as cell-type-dependent, or -independent DNA-methylation changes. In total, 158 regions were found to be differentially methylated in childhood asthma, all hypomethylated except for two, which includes a hypermethylated enhancer region for *TET*. Since TET proteins initiate DNA-demethylation, this DMR might be directly related to the global DNA-methylation aberrations observed in asthma. Whether this DMR in asthma is an initiating event or a compensatory mechanism remains to be elucidated in follow-up studies. The predominant global hypomethylation suggests a pronounced epigenetic activation affecting a variety of immune-related genes associated with asthma development and exacerbation. Here, with this first EWAS using a genome-wide sequencing approach and thus not relying on pre-selected CpGs as performed in previous asthma EWASs, we show that this epigenetic activation primarily affects enhancer elements indicating that a predominant enhancer activation underlies the exacerbated immune response characteristic of childhood asthma[47]. The tight connectivity of these epigenetically dysregulated asthma genes is evident in our inferred interaction network. A comprehensive search of the current scientific literature by NLP analytics revealed that while almost 34% of the enhancer target genes have already been associated with asthma or asthma-related terms, several of the enhancer-DMRs have not yet been discussed in the context of asthma. Most of the asthma-DMRs were enriched for multiple TFBS indicating multiple regulatory effects of the epigenetically perturbed regions. Most of the transcription factors binding to these DMR-enriched TFBS motifs are known to be associated with asthma, such as GATA3[44], NFACT1[48], IRF-1[49], GATA-6[50], STAT2[51], THB[52], or EGR1[53], and even possess a master regulatory capacity of Th2 differentiation[54,55].

LFA-1 is mainly known for its role in T cell adhesion and Th1 effector polarization. However, a recent report shows that LFA-1 and its ligand ICAM-1 are expressed on group 2 innate immune cells (ILC2). ILC2 are able to induce eosinophilic lung injury and are elevated in the blood of asthmatics compared to healthy controls[56]. Knock-down of LFA-1 or ICAM-1 both attenuated airway hyperresponsiveness, reduced airway inflammation and decreased lung ILC2 accumulation in mouse models of allergic asthma[57]. As such the observed cord blood DNA-hypomethylation of several regions involved in the LFA-1 signalling cascade might predispose children to a higher risk of allergic asthma.

The vast majority of DMRs was not associated with a meQTL indicating that mainly other than genetic factors contribute to the observed aberrant DNA-methylation in childhood asthma. About one third (35%) of the asthma-related DMRs were already found in cord blood. A variety of environmental insults experienced during the highly susceptible prenatal developmental phase - mostly related to maternal lifestyle factors during pregnancy - have been associated with an increased asthma risk of the child. A comparison to previous EWAS studies revealed that 22 of the asthma-related DMRs already identified in cord blood, including 17 differentially methylated enhancers, overlapped with DNA-methylation changes described in association to prenatal asthma risk factors (for references refer to Table S13B). Among others, these factors included maternal exposure to tobacco smoke or environmental chemicals as well as maternal health (e.g. gestational diabetes, preeclampsia). Although more studies are necessary to investigate whether these regions of persistent differential DNA-methylation are missing links between an adverse intrauterine environment and childhood asthma development, it is prudent to reduce these adverse exposures during vulnerable periods.

This study has to be seen in the light of some limitations. The sample size of whole-genome sequencing approaches seems to be low when compared to previous EWAS using less cost-intensive array based epigenetic profiling methods[5,8,58], however, in comparison to previous

WGBS studies[59-62] we included a considerable higher number of samples. In addition, the enrichment of the DMRs in the asthma pathway, the overlap between the DMR-associated genes with known asthma genes such as *IL4*, *EPX*, *IL5RA* and *ZFPM1* as identified by NLP, in conjunction with the overlap of previously reported CpG sites (e.g. *ACOT7*, *DEGS2*, *EPX* and *GATA2*) of asthma EWAS support the validity of the applied strategy to determine asthma-related DMRs. Although we confirmed the differential DNA-methylation of selected DMRs and their influence on associated target gene expression that are likely to contribute to asthma pathology in a larger sample set, further studies are needed to show whether the DMRs observed in our study can be replicated in independent cohorts and to determine the effect of the identified DMRs on the transcriptome. In addition, since more than half of the asthmatic children reported rhinitis or atopic dermatitis in their life, we cannot exclude that the observed asthma-related DMRs might also be influenced by other atopic diseases such as rhinitis or atopic dermatitis.

The whole blood-based sequencing of DNA-methylation might be seen as a further limitation. To overcome this problem, the proportion of the different cell populations was determined by a deconvolution approach and the DMRs annotated with respect to their cell-type dependency. The deconvolution approach might have led to misclassification or underrepresentation of minor cell types. However, we were able to annotate the small population of eosinophils and to show a significant difference in the eosinophil count between children with asthma and controls without respiratory disease. For a global overview of aberrant DNA-methylation changes and an unbiased interpretation of EWAS[63], we deem the here utilized approach more appropriate, i.e., not to adjust for cell-type composition beforehand, but rather to determine all DMRs and subsequently annotate them as cell-type-dependent or genotype-associated.

To our best knowledge, this is the first study evaluating the children's methylome at single base-pair resolution – including the comprehensive information on the genetic background - using repeatedly collected samples of the same individual. We were able to confirm our findings in a larger sample set of two cohorts and showed functional translation to the transcriptional and

protein level for selected DMRs. We identified global DNA-methylation changes particularly affecting enhancers, which likely contribute to an altered gene expression of key immune genes involved in asthma pathology. Most of the immune system-related epigenetic alterations including the hypomethylated *IL-4* enhancer, or the *IL5RA* promoter are not present in cord blood, supporting the notion that they are developed during the shift of the immune response toward a Th2 reactivity contributing to the development of an atopic asthma phenotype. Although most of the cord blood DMRs are not directly related to the immune dysfunction characterizing the asthmatic phenotype, these regions related to genes involved in LFA-1 signaling. In light of the emerging role of LFA-1 in ILC2 modulated allergic asthma, these cord blood DNA-methylation changes might be involved in predisposing children to a higher risk for asthma development. Future studies will show if these regions have the ability to predict high-risk children.

Acknowledgment

We cordially thank the participants of the LINA, LISA and PASTURE cohorts, as well as Beate Fink, Anne Hain, Michaela Loschinski, Melanie Bänsch and Maik Schilde for their excellent technical assistance and field work. We are grateful for the major support provided by the Division of Theoretical Bioinformatics, and the Heidelberg Center for Personalized Oncology, DKFZ-HIPO of the German Cancer Research Center (DKFZ) in Heidelberg, Germany.

Author contribution

IL, RE, MKa, and ST provided project leadership.

AvB, BS, JH, MB, SR, EvM, JR, ADC, RL, MKa, AMK, IL, GH were involved in the recruitment and field work of the cohorts.

GH provided cytokine data.

MB provided the RNA transcription data.

SDM, MK, MB, TB, and CH performed the DMR calling and DMR annotation.

MK, LT, DW, OM, and CP performed or guided targeted methylation analyses.

MK, SDM, MM, MB, NI, TB, CH, ST, GS, and LT performed or supervised data analysis.

SS, EF, UH, MK and ST performed or evaluated NLP analysis.

LT, ST, MK, and IL wrote the manuscript.

All authors were involved in the discussion and contributed to the final manuscript.

Figure captions

Figure 1: Study design. Blood samples derived from asthmatics or control children of the three cohorts were subjected to WGBS to determine asthma-related DMRs. DMRs comparing asthmatic and control children were determined by the two independent DMR-calling algorithms DSS and metilene. Asthma-related DMRs were subsequently analysed.

DMR = differentially methylated region, WGBS = whole-genome bisulfite sequencing, LINA = lifestyle and environmental factors and their influence on newborns allergy risk, LISA = influences of lifestyle-related factors on the immune system and the development of allergies in childhood, PASTURE = Protection Against Allergy: Study in Rural Environments

[1] based on available cord blood sample of LINA and PASTURE

[2] based on available whole blood samples of LINA and LISA

[3] based on available plasma samples of LINA

Figure 2: DMR distribution and down-stream analyses. (A) Circos plot represents the distribution of the 158 differentially methylated regions (DMRs) identified in asthmatic children vs. controls across all autosomes. The outer circle shows the 22 autosomes. The bars in the inner circle represent the DMRs and their chromosomal location. Hypermethylated DMRs are indicated as red bars, hypomethylated DMRs in blue. The height of each bar indicates the DNA-methylation differences between asthmatics and controls. **(B)** KEGG pathway enrichment for all asthma-DMRs based on their genomic location. **(C)** DNA-methylation difference between asthmatic children and controls of the WGBS samples (asthma n=40, controls n=42), LINA study (asthma n=19, controls n=108) and LISA study (asthma n=25, controls n=115) for DMRs related to *EPX* and *IL5RA* as determined by sequencing or MassARRAY, respectively (*p*-value from Mann-Whitney U-test, r_{pb}:

point biserial correlation coefficient). **(D)** Association of *EPX* and *IL5RA* DNA-methylation (black whiskers) and transcription (magenta whiskers) to asthma outcome in meta-analysis combining LINA and the LISA study (DNA-methylation: asthma n=44, controls n=223, *EPX* transcription: asthma n=44, controls n=220, *IL5RA* transcription: n=44 asthma n=222 controls). Given are ORs with +/-95% CIs from logistic regression adjusted for child's sex, cohort, prenatal tobacco smoke exposure, family history of atopy, parental school education and maternal age at birth using ln-transformed DNA-methylation values.

Figure 3: Genomic location of asthma-related DMRs and functional translation of *IL4* enhancer hypomethylation. (A) Pie chart represents the proportional distribution of the genomic regions affected by asthma-related DMRs. **(B)** Genomic location of the *IL4* DMR and the genomic region analysed by MassARRAY in the UCSC genome browser[64]. **(C)** Scatterplots show the association of *IL4* DNA-methylation to *IL4* transcription (n=112) and IL-4 protein concentration (n=115) and the association of IL-4 protein concentration to *IL4* transcription (n=111) in six-years-old children of the LINA study. Correlation coefficient (ρ) and p-value from Spearman correlation. **(D)** Mediation analysis for the relationship of *IL4* enhancer DNA-methylation, *IL4* transcription, and IL-4 protein concentration of six-years-old children of LINA (n=111). Model was adjusted for child's sex, prenatal tobacco smoke exposure, family history of atopy, parental school education and maternal age at birth. IL-4 protein concentrations were determined after PHA-stimulation. Protein and DNA-methylation data were ln-transformed before analysis. Effect sizes for indirect path is given as standardized β-values with +/-95% CIs. Significance determined by bias-corrected bootstrapping.

MA = MassARRAY, DMR = differentially methylated region

Figure 4: Network module analysis of asthma-DMR associated genes. Shown are all asthma-DMR associated genes, which show a predicted or experimentally based interaction. Only modules with more than one connection are shown. Target genes of enhancers affected by a DMR are highlighted by blue outline circles. Genes related to asthma or similar terms as determined by the natural language processing tool are indicated in red font. Module nomenclature is based on subsequent pathway enrichment analysis (Table S12).

Figure 5: Cord blood asthma-DMRs. (A) Matched cord blood samples were subjected to WGBS to determine the DNA-methylation level of the asthma-related DMRs at time of birth in control children compared to those children who later developed asthma. **(B)** Pie charts represent the portion of genotype-, and non-genotype-associated DMRs (g/ngDMRs) and those DMRs, which were already differentially methylated in cord blood samples (=cord blood DMRs). The table lists all prenatal influencing factors that have previously been associated with CpGs included in the n=56 cord blood asthma-related DMRs (see Table S6C for EWAS references and cord blood DMR list). Genes highlighted in red font were described with asthma as identified by natural language processing (see Table S13B for references). #ngDMRs indicated with light blue and gDMR with dark blue background. *Enhancer target genes were derived from GeneHancer, in cases where no GeneHancer annotation was available the closest TSS gene is given. **(C)** Network module analysis for cord blood DMR associated genes (left panel) and for genes associated to DMRs only present in asthma phenotype (right panel). Only modules with more than one connection are shown. Module nomenclature is based on network of Figure 4.

PFOS = perfluorooctane sulfonic acid, NLP = natural language processing

Figure S1: Literature search for overlap of DMRs with previous EWAS. (A) Workflow summarizes the EWAS studies investigated asthma-related outcomes, which were used for the overlap with n=158 asthma-related DMRs. **(B)** Workflow summarizes the EWAS studies investigated prenatal influencing factors, which were used for the overlap with n=56 cord blood asthma-related DMRs.

Figure S2: Quality control of the MassARRAY amplicons. Graphs show DNA-methylation values derived by MassARRAY measurements of standard samples (0%, 20%, 40%, 60%, 80%, and 100% methylated genomic DNA) representing the mean DNA-methylation of the MassARRAY amplicon for **(A)** *IL5RA* (including 7 CpGs), **(B)** *EPX* (including 9 CpGs) and **(C)** *IL4* (including 6 CpGs) DMR (given are mean ±SD of two replicates and r^2 from linear regression).

Figure S3: Study workflow. DMRs comparing asthmatics and control children of three cohorts were called by two independent algorithms (DSS, metilene) and concordant DMRs were subjected to multiple test corrected factorial ANOVA analysis to determine asthma-related DMRs. These 158 DMRs were subsequently analysed and categorized based on their dependency on the genotype, the cell type composition or their presence also in cord blood.
DMR = differentially methylated region, ng/gDMR = non-genotype/genotype-associated DMRs

Figure S4: Characteristics of asthma-related DMRs. (A) Cluster analysis with ß-methylation values of the 158 asthma-related DMRs. **(B)** CoMET plot of the validated *EPX* and *IL5RA* DMR. Plots show WGBS derived β-methylation values of asthmatics vs. control children on top (n=40 vs. 42, mean +/-SEM) followed by *p*-values from logistic regression analysis (asthma phenotype ~

β-values) and UCSC tracks (ENSEMBL genes, CpG islands, DNAse-sensitive regions and SNPs) as well as the DNA-methylation correlation matrix for all CpG sites within the DMRs.

Figure S5: Epigenetic regulation of *IL5RA* and *EPX* transcription in asthma. (A) Correlation between *IL5RA* and *EPX* DNA-methylation to *IL5RA*/*EPX* transcription of children of the LINA (magenta) and LISA (black) study. Correlation coefficient ρ and p-value from Spearman correlation~~Indicated is Spearman correlation~~. **(B)** Relative gene expression of *IL5RA* and *EPX* in asthmatic children and controls participated in LINA (asthma n=19, controls n=107) or LISA (*IL5RA*: asthma n=25, controls n=115, *EPX:* asthma n=25, controls n=113). p-value from Mann-Whitney U-test, r_{pb}: point biserial correlation coefficient.

Figure S6: IL-4 protein and *IL4* enhancer hypomethylation in asthma. Illustrated is the mediation model adjusted for child's sex, prenatal tobacco smoke exposure, family history of atopy, parental school education and maternal age at birth. Effect sizes for the indirect path is given as standardized β-values with +/-95% bias-corrected bootstrap CIs (n=111, significant as determined by bootstrap CI). The analysis is shown for the LINA subcohort with available PHA-stimulated IL-4 protein concentrations. Protein and DNA-methylation data were ln-transformed before analysis.

METHODS

Cohort description

LINA cohort

For the prospective mother-child cohort LINA (Lifestyle and environmental factors and their Influence on Newborns Allergy risk) 629 mother-child pairs (622 mothers and 629 children; 7 twins) were recruited between March 2006 and December 2008 in Leipzig, Germany. Cord blood and whole blood samples from children were obtained annually during clinical visits until the age of six years and at the age of eight years. Standardized questionnaires assessing lifestyle factors, and children's disease outcomes were self-administered by the parents during pregnancy (34th week of gestation) and annually thereafter[1].

LISA cohort

This study is based on the 15-years follow-up of LISAplus (Influences of Lifestyle-related factors on the Immune System and the Development of Allergies in Childhood). LISA is a prospective birth cohort, for which 3,097 newborns were recruited during November 1997 and January 1999 at four different study centers in Germany (Munich, Leipzig, Wesel, and Bad Honnef). Blood samples were obtained at birth, age two, six, 10, and 15 during clinical visits. Note that no genomic DNA of cord blood samples was available for the LISA study. Standardized questionnaires were answered by the parents at each follow-up and complemented by questionnaires self-administered by the children at age 15[2].

The PASTURE cohort

This study used samples and data of the time of birth and the six-year follow-up of PASTURE (Protection Against Allergy: Study in Rural Environments). PASTURE is a prospective birth cohort study comprising participants from five European countries (Austria, Finland, France,

Germany, and Switzerland) including 1,133 mother-child pairs, which were recruited between August 2002 and March 2005[3]. Standardized questionnaires were answered by parents during pregnancy, at the time of birth, and every subsequent year until the age of six years. Cord blood and whole blood samples were collected at birth, age one, age 4.5 years and age six during clinical visits.

Genomic DNA extraction and bisulfite-conversion

Genomic DNA (gDNA) was isolated from whole blood and cord blood samples using the DNeasy Blood & Tissue Kit (Qiagen, Hilden, Germany) following manufactures instructions. For DNA-methylation analysis by MassARRAY and WGBS, gDNA was bisulfite converted according to the manufacturer´s protocol using the EZ DNA Methylation Kit (Zymo Research, Freiburg, Germany), the EZ DNA Methylation-Lightning Kit (Zymo Research, Freiburg, Germany), and the EpiTect Bisulfite Kit (Qiagen, Hilden, Germany), respectively.

Whole-genome bisulfite sequencing (WGBS)

Libraries were prepared using the TruSeq DNA Sample Prep Kit v2-Set A (Illumina Inc., San Diego, CA, USA) and EpiTect Il TruSeq DNA (Illumina Inc., San Diego, CA, USA) according to the manufacturer's instructions. Adapter-ligated libraries were bisulfite-treated and PCR-amplified. Whole-genome sequencing was performed on HiSeq2000 (three lanes, 101-bp paired-end) or Illumina HiSeq X Ten V2.5 (2 lanes,150 bp) using standard Illumina protocols and the 200-cycle TruSeq SBS Kit v3, and HiSeq X Ten Reagent Kit v2.5 (Illumina Inc., San Diego, CA, USA; Table S2). Reads were aligned against the phase II reference sequence of the 1000 genomes project including decoy sequences (ftp://ftp.1000genomes.ebi.ac.uk/vol1/ftp/technical/reference/phase2_reference_assembly_sequence/hs37d5.fa.gz). Since DNA sequences were bisulfite-converted, a special alignment protocol adapted for whole-genome bisulfite sequencing data was followed (using

methylCTools: https://github.com/hovestadt/methylCtools). In brief, the reference sequence was *in-silico* bisulfite converted. The same procedure was performed for the sequencing reads, but the original bases were stored. Afterward, the reads were aligned against the converted reference forward and reverse strands using BWA mem (version:0.7.8)[4]. Duplicate reads were removed using sambamba (version: 0.5.9)[5]. The aligned reads were back-transformed into their original state and methylation ratios were called per reference CpG site.

Definition of genotype-associated DMRs

Genotype-associated DMRs (gDMRs) were determined according to previous works[1,6]. Briefly, SNPs were called using Bis-SNP (version 0.81.2) applying default parameter settings[7]. For analysis, we considered all SNPs from dbSNP version 141[8]. *P*-value correction was performed using the Benjamini-Hochberg procedure with a 10% False Discovery Rate (FDR). Whenever a significant correlation (Spearman) of any SNP in a +/-5 kb window around the DMR to the mean DMR methylation was observed, the corresponding DMR was categorized as genotype-associated. Likewise, DMRs with no meQTL were classified as a non-genotype associated DMR (ngDMR).

Cell-type deconvolution from DNA-methylation

Blood cell type fractions within the convoluted methylation signals from whole blood were estimated using the *EpiDISH* R-package version 2.6.1[9-14]. Since EpiDISH uses as a reference data set originated from EPIC Array methylation data of sorted blood cell types (B cells, NK cells, $CD4^+$ T cells, $CD8^+$ T cells, monocytes, neutrophils, and eosinophils), WGBS methylation data were preprocessed prior to deconvolution. Briefly, WGBS methylation data were restricted to CG positions profiled on the EPIC Array. CG positions that were covered by less than ten reads or overlap with a SNP were removed. SNP calling on the WGBS data was performed using Bis-SNP software (version 0.81.2)[7]. The filtered methylation matrix was then

used to perform cell fraction estimation. Here, the function EpiDISH was used from the EpiDISH R-package where the filtered methylation matrix was assigned to the argument beta.m, and the reference matrix centDHSbloodDMC.m that was loaded from the EpiDISH R-package and assigned to the argument ref.m. As method for cell fraction estimation Robust Partial Correlations was used.

Definition of cell-type composition-dependent DMRs

Frequencies of blood cells including T cells, B cells, NK cells, monocytes, neutrophils, and eosinophils were estimated by cell-type deconvolution as aforementioned. Adjusted multiple regression models (confounder: child's sex, cohort, prenatal tobacco smoke exposure, family history of atopy, parental school education, maternal age at birth, growing up on a farm) with the mean DNA-methylation of the DMR as the dependent variable and the specific cell type estimates ($CD4^+$ T cells, $CD8^+$ T cells, B cells, NK cells, monocytes, neutrophils or eosinophils) as the independent variable was applied to assess cell-type dependent DMRs. Whenever an asthma-related DMR was significantly (Bonferroni-corrected $p<.05$, corresponding to a nominal $p<.00032$) associated with a specific blood cell type frequency, the corresponding DMR was categorized as a cell-type-dependent DMR.

Enhancer enrichment analysis of DMRs

To investigate the enrichment of known enhancers regions in DMRs against genomic background regions, we used Fisher's exact test implemented in the python scipy package. Genomic background regions were generated by merging CpGs that were at most 100 bp apart from each other. Further, regions that had less than three CpGs or overlapped with the DMRs were removed. The parameters chosen to create the background regions is similar to the parameters used for DMR calling and should give a reasonable set of background regions.

DNA-methylation analysis by MassARRAY

Bisulfite-converted DNA of six-, eight-year-old children of the LINA cohort and of 15-year-old children from the LISA cohort was PCR amplified using HotStarTag DNA Polymerase (Qiagen, Hilden, Germany) with the following cycling program: 95°C for 15 min, followed by 45 cycles at 94°C for 30 s, 52/56°C for 30 s, 72 °C for 1 min and a final elongation step at 72°C for 5 min (see Table S4 for primer sequences and primer-specific annealing temperature). The PCR product was *in vitro* transcribed, cleaved by RNase A using the EpiTyper T Complete Reagent Set (Agenea Bioscience, CA, USA), and subjected to MALDI-TOF mass spectrometry analysis to determine DNA-methylation levels. DNA-methylation standards (0%, 20%, 40%, 60%, 80%, 100% methylated genomic DNA) were used to control for potential PCR bias (Supplementary Fig. 2).

RNA isolation, cDNA synthesis, and qPCR

For transcriptional analysis of *EPX*, *IL4* and *IL5RA*, total RNA of the blood was extracted by PAXgene Blood RNA kit (Qiagen, Hilden, Germany) and reverse transcribed using the ImProm-II™ Reverse Transcription System (Promega, Mannheim, Germany) according to the manufacturer's instructions. Gene expression was measured on the Biomark HD system using Universal ProbeLibrary (UPL) hydrolysis probes (Roche Life Sciences, Germany) and 96.96 Dynamic Arrays (Fluidigm, San Francisco, CA, USA) as previously described (6) (see Table S5 for qPCR primer sequences). All reactions were performed in triplicates. Gene expression values were determined by the $2^{-\Delta\Delta CT}$ method with *GAPD*, *PGK1*, and *GUSB*, as reference genes and normalized to the lowest measured value.

Cytokine measurement

Heparinized whole blood of six year-old participants of the LINA study were used to measure IL-4 concentration in pg/ml as previously described[15]. Briefly, whole blood (500µl) was stimulated 4 h at 37°C with the mitogen phytohemagglutinin (PHA, 50 µg/ml; Sigma Aldrich, Hamburg, Germany) and then diluted 1:1 with RPMI1640 medium without supplements. Samples were centrifuged and the supernatant was measured by flow cytometry using cytometric bead array (BD CBA Human Soluble Flex Set system, Becton Dickinson, Heidelberg, Germany) according to manufactures protocol. The detection limit was 3 pg/ml. Values below the limit of detection were set as half of detection limit.

Natural Language Processing of network genes

First, target gene names included in the network analysis were mapped to human NCBI Gene identifiers by symbol, name, or synonym. In case more than one NCBI Gene ID was identified, target gene names were matched to GeneRIF data[16], which are brief descriptions of gene functions frequently containing the respective gene name. Matches with GeneRIF were subsequently scored with Lucene's[17] BM25[18] implementation. The match with the highest score was used as the candidate target gene.

The BANNER[19] gene tagger was employed to identify any gene name mentioned in any publication listed in the PubMed and PubMed Central open access literature databases. The resulting document set was filtered by the terms “asthma”, “asthmatic”, “asthmatics”, “wheeze”, “bronchial hyperreactivity”, “airway hyperreactivity”, “bronchial hyperresponsiveness”, or “hyperreactive airway disease” co-occurring in the same sentence or the same paragraph with the already identified gene name (query date: November, 2022). Lastly, the mapped NCBI Gene IDs of the target genes were matched to the IDs extracted from the literature in the same manner as described above to filter the literature for sought genes.

Literature search of EWAS related to asthma or prenatal influencing factors

To identify previously published EWAS studies that investigated the effect of prenatal influencing factors or EWAS investigated asthma-related outcomes, we performed a literature search in PubMed.

Previous asthma-outcome associated EWAS studies in the PubMed database were identified by the search term: ("asthma" OR "wheeze") AND ("WGBS" OR "EWAS" OR "450k" OR "850k" OR "27k" OR "epigenome-wide" OR "HumanMethylation450K BeadChip") AND "blood" (query data 27.10.2022). This search retrieved n=68 publications, from which two reviews, one RCT and one systematic review were excluded. After manual curation n=22 EWAS studies (including meta-analyses) remained that reported DNA-methylation changes in blood related to asthma or lung function (Figure S1A).

Previous EWAS studies investigating prenatal influencing factors affecting DNA-methylation in cord blood in the PubMed database were identified by the search term: „DNA methylation" AND ("WGBS" OR "EWAS" OR "450k" OR "850k" OR "27k" OR "epigenome-wide" OR "HumanMethylation450K BeadChip")) AND ("prenatal" OR "utero" OR "maternal" OR "cord blood" OR "birth") (query date: 25.04.2022). Only EWAS studies that used array-based (Illumina's HumanMethylation 27/450/850k BeadChips) or sequencing approaches were considered. A total of n=376 studies were identified. Subsequently, these n=376 papers were independently screened by two researchers to select only original studies conducted with cord blood samples. Additionally, studies examining only prospective outcomes, or those that described solely sex-related DNA-methylation differences were excluded. This resulted in n=89 EWAS of which five studies were excluded, since no significant DNA-methylation changes were described, leaving n=84 EWAS for overlap analysis with cord-blood asthma-related DMRs (Supplementary Fig. 1B).

METHODS

Cohort description

LINA cohort

For the prospective mother-child cohort LINA (Lifestyle and environmental factors and their Influence on Newborns Allergy risk) 629 mother-child pairs (622 mothers and 629 children; 7 twins) were recruited between March 2006 and December 2008 in Leipzig, Germany. Cord blood and whole blood samples from children were obtained annually during clinical visits until the age of six years and at the age of eight years. Standardized questionnaires assessing lifestyle factors, and children's disease outcomes were self-administered by the parents during pregnancy (34th week of gestation) and annually thereafter[1].

LISA cohort

This study is based on the 15-years follow-up of LISAplus (Influences of Lifestyle-related factors on the Immune System and the Development of Allergies in Childhood). LISA is a prospective birth cohort, for which 3,097 newborns were recruited during November 1997 and January 1999 at four different study centers in Germany (Munich, Leipzig, Wesel, and Bad Honnef). Blood samples were obtained at birth, age two, six, 10, and 15 during clinical visits. Note that no genomic DNA of cord blood samples was available for the LISA study. Standardized questionnaires were answered by the parents at each follow-up and complemented by questionnaires self-administered by the children at age 15[2].

The PASTURE cohort ~~– EFRAIM study group~~

This study used samples and data of the time of birth and the six-year follow-up of PASTURE (Protection Against Allergy: Study in Rural Environments~~)/EFRAIM.~~). PASTURE~~/EFRAIM~~ is a prospective birth cohort study comprising participants from five European countries

(Austria, Finland, France, Germany, and Switzerland) including 1,133 mother-child pairs, which were recruited between August 2002 and March 2005[3]. Standardized questionnaires were answered by parents during pregnancy, at the time of birth, and every subsequent year until the age of six years. Cord blood and whole blood samples were collected at birth, age one, age 4.5 years and age six during clinical visits.

Genomic DNA extraction and bisulfite-conversion

Genomic DNA (gDNA) was isolated from whole blood and cord blood samples using the DNeasy Blood & Tissue Kit (Qiagen, Hilden, Germany) following manufactures instructions. For DNA-methylation analysis by MassARRAY and WGBS, gDNA was bisulfite converted according to the manufacturer´s protocol using the EZ DNA Methylation Kit (Zymo Research, Freiburg, Germany), the EZ DNA Methylation-Lightning Kit (Zymo Research, Freiburg, Germany), and the EpiTect Bisulfite Kit (Qiagen, Hilden, Germany), respectively.

Whole-genome bisulfite sequencing (WGBS)

Libraries were prepared using the TruSeq DNA Sample Prep Kit v2-Set A (Illumina Inc., San Diego, CA, USA) and EpiTect Il TruSeq DNA (Illumina Inc., San Diego, CA, USA) according to the manufacturer's instructions. Adapter-ligated libraries were bisulfite-treated and PCR-amplified. Whole-genome sequencing was performed on HiSeq2000 (three lanes, 101-bp paired-end) or Illumina HiSeq X Ten V2.5 (2 lanes,150 bp) using standard Illumina protocols and the 200-cycle TruSeq SBS Kit v3, and HiSeq X Ten Reagent Kit v2.5 (Illumina Inc., San Diego, CA, USA; Table S2). Reads were aligned against the phase II reference sequence of the 1000 genomes project including decoy sequences (ftp://ftp.1000genomes.ebi.ac.uk/vol1/ftp/technical/reference/phase2_reference_assembly_sequence/hs37d5.fa.gz). Since DNA sequences were bisulfite-converted, a special alignment protocol adapted for whole-genome bisulfite sequencing data was followed (using

methylCTools: https://github.com/hovestadt/methylCtools). In brief, the reference sequence was *in-silico* bisulfite converted. The same procedure was performed for the sequencing reads, but the original bases were stored. Afterward, the reads were aligned against the converted reference forward and reverse strands using BWA mem (version:0.7.8)[4]. Duplicate reads were removed using sambamba (version: 0.5.9)[5]. The aligned reads were back-transformed into their original state and methylation ratios were called per reference CpG site.

Definition of genotype-associated DMRs

Genotype-associated DMRs (gDMRs) were determined according to previous works[1,6]. Briefly, SNPs were called using Bis-SNP (version 0.81.2) applying default parameter settings[7]. For analysis, we considered all SNPs from dbSNP version 141[8]. *P*-value correction was performed using the Benjamini-Hochberg procedure with a 10% False Discovery Rate (FDR). Whenever a significant correlation (Spearman) of any SNP in a +/-5 kb window around the DMR to the mean DMR methylation was observed, the corresponding DMR was categorized as genotype-associated. Likewise, DMRs with no meQTL were classified as a non-genotype associated DMR (ngDMR).

Cell-type deconvolution from DNA-methylation

Blood cell type fractions within the convoluted methylation signals from whole blood were estimated using the *EpiDISH* R-package version 2.6.1[9-14]. Since EpiDISH uses as a reference data set originated from EPIC Array methylation data of sorted blood cell types (B cells, NK cells, $CD4^+$ T cells, $CD8^+$ T cells, monocytes, neutrophils, and eosinophils), WGBS methylation data were preprocessed prior to deconvolution. Briefly, WGBS methylation data were restricted to CG positions profiled on the EPIC Array. CG positions that were covered by less than ten reads or overlap with a SNP were removed. SNP calling on the WGBS data was performed using Bis-SNP software (version 0.81.2)[7]. The filtered methylation matrix was then

used to perform cell fraction estimation. Here, the function EpiDISH was used from the EpiDISH R-package where the filtered methylation matrix was assigned to the argument beta.m, and the reference matrix centDHSbloodDMC.m that was loaded from the EpiDISH R-package and assigned to the argument ref.m. As method for cell fraction estimation Robust Partial Correlations was used.

Definition of cell-type composition-dependent DMRs

Frequencies of blood cells including T cells, B cells, NK cells, monocytes, neutrophils, and eosinophils were estimated by cell-type deconvolution as aforementioned. ~~To adjust the DMRs for the general cell-type heterogeneity and to account for a potential underlying shift in the granulocyte-to-lymphocyte ratio between asthmatics and controls, the proportions of NK-, T-, B cells, and monocytes, neutrophils, eosinophils were combined to lymphoid-, and myeloid cells, respectively [15].~~ Adjusted multiple regression models (confounder: ~~age,~~ child's sex, ~~recruitment location~~cohort, prenatal tobacco smoke exposure, family history of atopy, parental school education, maternal age at birth, growing up on a farm) with the mean DNA-methylation of the DMR as the dependent variable and the ~~proportion of lymphoid cells~~specific cell type estimates ($CD4^+$ T cells, $CD8^+$ T cells, B cells, NK cells, monocytes, neutrophils or eosinophils) as the independent variable was applied to assess cell-type dependent DMRs. ~~In a second model, the eosinophil count was included instead of the lymphoid/myeloid ratio.~~ Whenever an asthma-related DMR was significantly (Bonferroni-corrected $p<.05$, corresponding to a nominal $p<.00032$) associated with ~~eosinophil~~a specific blood cell type frequency ~~and the lymphoid/myeloid ratio (Bonferroni-corrected $p<0.00031$), the~~, the corresponding DMR was categorized as ~~an eosinophil, or~~ a cell-~~composition~~type-dependent DMR~~, respectively~~.

Enhancer enrichment analysis of DMRs

To investigate the enrichment of ~~DMRs within~~ known ~~enhancer~~enhancers regions~~, we applied the algorithm/R package Locus Overlap Analysis (LOLA) (version 1.16.0) [16]. LOLA is based on a Fisher's exact test, to check if the ratio of foreground features (~~ in ~~our case DMRs) that overlap with a list of regions of interest (ROIs) is enriched~~ DMRs against ~~the ratio of~~genomic background ~~features that overlap with a list of ROIs. We calculated~~regions, we used Fisher's exact test implemented in the ~~set of~~python scipy package.

Genomic background ~~features~~regions were generated by merging ~~CpG positions among the whole genome that have a distance of smaller or equal to~~ CpGs that were at most 100 bp~~. In a second step, we removed all merged regions~~ apart from ~~further analysis~~each other. Further, regions that ~~consist of~~had less than three ~~CpG sites.~~CpGs or overlapped with the DMRs were removed. The ~~definition of our~~ parameters chosen to create the background ~~set of features reflects~~regions is similar to the parameters used for DMR calling and ~~ensures that the foreground~~should give a reasonable set of ~~features is a subset of the~~ background ~~set of features~~regions.

DNA-methylation analysis by MassARRAY

Bisulfite-converted DNA of six-, eight-year-old children of the LINA cohort and of 15-year-old children from the LISA cohort was PCR amplified ~~(for primer sequences see Table S4)~~ using HotStarTag DNA Polymerase (Qiagen, Hilden, Germany) with the following cycling program: 95°C for 15 min, followed by 45 cycles at 94°C for 30 s, 52/56°C for 30 s, 72 °C for 1 min and a final elongation step at 72°C for 5 min (see Table S4 for primer sequences and primer-specific annealing temperature). The PCR product was *in vitro* transcribed, cleaved by RNase A using the EpiTyper T Complete Reagent Set (Agenea Bioscience, CA, USA), and subjected to MALDI-TOF mass spectrometry analysis to determine DNA-methylation levels. DNA-methylation standards (0%, 20%, 40%, 60%, 80%, 100% methylated genomic DNA) were used to control for potential PCR bias (Supplementary Fig. 2).

RNA isolation, cDNA synthesis, and qPCR

For transcriptional analysis of *EPX*, *IL4* and *IL5RA*, total RNA of the blood was extracted by PAXgene Blood RNA kit (Qiagen, Hilden, Germany) and reverse transcribed using the ImProm-II™ Reverse Transcription System (Promega, Mannheim, Germany) according to the manufacturer's instructions. Gene expression was measured on the Biomark HD system using Universal ProbeLibrary (UPL) hydrolysis probes (Roche Life Sciences, Germany) and 96.96 Dynamic Arrays (Fluidigm, San Francisco, CA, USA) as previously described (6) (see Table S5 for qPCR primer sequences). All reactions were performed in triplicates. Gene expression values were determined by the $2^{-\Delta\Delta CT}$ method with *GAPD*, *PGK1*, and *GUSB*, as reference genes and normalized to the lowest measured value.

Cytokine measurement

Heparinized whole blood of six year-old participants of the LINA study were used to measure IL-4 concentration in pg/ml as previously described[15]. Briefly, whole blood (500µl) was stimulated 4 h at 37°C with the mitogen phytohemagglutinin (PHA, 50 µg/ml; Sigma Aldrich, Hamburg, Germany) and then diluted 1:1 with RPMI1640 medium without supplements. Samples were centrifuged and the supernatant was measured by flow cytometry using cytometric bead array (BD CBA Human Soluble Flex Set system, Becton Dickinson, Heidelberg, Germany) according to manufactures protocol. The detection limit was 3 pg/ml. Values below the limit of detection were set as half of detection limit.

Natural Language Processing of network genes

First, target gene names included in the network analysis were mapped to human NCBI Gene identifiers by symbol, name, or synonym. In case more than one NCBI Gene ID was identified, target gene names were matched to GeneRIF data[16], which are brief descriptions of gene

functions frequently containing the respective gene name. Matches with GeneRIF were subsequently scored with Lucene's[17] BM25[18] implementation. The match with the highest score was used as the candidate target gene.

The BANNER[19] gene tagger was employed to identify any gene name mentioned in any publication listed in the PubMed and PubMed Central open access literature databases. The resulting document set was filtered by the terms “asthma”, “asthmatic”, “asthmatics”, “wheeze”, “bronchial hyperreactivity”, “airway hyperreactivity”, “bronchial hyperresponsiveness”, or “hyperreactive airway disease” co-occurring in the same sentence or the same paragraph with the already identified gene name (query date: November, 2022). Lastly, the mapped NCBI Gene IDs of the target genes were matched to the IDs extracted from the literature in the same manner as described above to filter the literature for sought genes.

Literature search of EWAS related to asthma or prenatal influencing factors

To identify previously published EWAS studies that investigated the effect of prenatal influencing factors ~~affecting DNA-methylation in cord blood that might overlap with our~~or EWAS investigated asthma-related ~~cord blood DMRs~~outcomes, we performed a literature search in PubMed ~~(query date: 25.04.2022) for previously published EWAS studies. Only~~. Previous asthma-outcome associated EWAS studies ~~that used array-based (Illumina’s HumanMethylation 27/450/850k BeadChips) or sequencing approaches were considered. A total of n=376 studies~~ in the PubMed database were identified by ~~using~~the search term: ("asthma" OR "wheeze") AND ("WGBS" OR "EWAS" OR "450k" OR "850k" OR "27k" OR "epigenome-wide" OR "HumanMethylation450K BeadChip") AND "blood" (query data 27.10.2022). This search retrieved n=68 publications, from which two reviews, one RCT and one systematic review were excluded. After manual curation n=22 EWAS studies (including meta-analyses) remained that reported DNA-methylation changes in blood related to asthma or lung function (Figure S1A).

Previous EWAS studies investigating prenatal influencing factors affecting DNA-methylation in cord blood in the PubMed database were identified by the search term: „DNA methylation" AND ("WGBS" OR "EWAS" OR "450k" OR "850k" OR "27k" OR "epigenome-wide" OR "HumanMethylation450K BeadChip")) AND ("prenatal" OR "utero" OR "maternal" OR "cord blood" OR "birth~~").~~") (query date: 25.04.2022). Only EWAS studies that used array-based (Illumina's HumanMethylation 27/450/850k BeadChips) or sequencing approaches were considered. A total of n=376 studies were identified. Subsequently, these n=376 papers were independently screened by two researchers to select only original studies conducted with cord blood samples. Additionally, studies examining only prospective outcomes, or those that described solely sex-related DNA-methylation differences were excluded. This resulted in n=89 EWAS of which five studies were excluded, since no significant DNA-methylation changes were described, leaving n=84 EWAS for overlap analysis with cord-blood asthma-related DMRs (~~Figure S1).~~Supplementary Fig. 1B).

Definition for intersection of DMR with enhancer
intersection (at least 1bp) between known ENCODE enhancer and DMRs
intersection (at least 1bp) between known ROADMAP enhancer of blood or T-cell sets (n=14*) and DMRs
intersection (at least 1bp) between known ROADMAP enhancer of HSC or B-cell sets (n=9**) and DMRs
intersection (at least 1bp) between active marks of LINA children (according to Bauer et al.) and DMRs
intersection (at least 1bp) between known GeneHancer enhancer and DMRs

GWAS trait[#]
Appendicular lean mass, Height, **Lung function (FVC)**
Developmental language disorder (linguistic errors)
Educational attainment
educational attainment, Brain region volumes
Electrocardiogram morphology (amplitude at temporal datapoints), **Lung function (FVC)**, Appendicular lean mass, Height

Hand grip strength

Left–right brain asymmetry, Brain shape (segment 3), Cortical thickness, Vertex-wise cortical thickness, Cortical surface area, brain measurement

Number of sexual partners, Longevity, Refractive error, **Idiopathic pulmonary fibrosis**

PCA3 expression level, Celiac disease, Prostate cancer

Protein quantitative trait loci, Inflammatory skin disease, Platelet-to-lymphocyte ratio, **Lymphocyte counts**, Serum levels of protein ICAM5, Sex hormone-binding globulin levels adjusted for BMI, Blood protein levels

Psoriatic arthritis, Crohn's disease, Leprosy, L1-L4 bone mineral density x serum urate levels interaction, Sarcoidosis, QT interval in Tripanosoma cruzi seropositivity

Spherical equivalent, **Lung Function (FVC)**, Estimated glomerular filtration rate (creatinine), Hip circumference adjusted for BMI

Basophil count, White blood cell count (basophil), White blood cell count (eosinophil), White blood cell count, leukocyte count, Neutrophil percentage of white cells, eosinophil percentage of leukocytes, eosinophil count

Table S12: Module pathway enrichment

(B) BioCarta
(R) Reactome
(N) Pathway Interaction Database
(K) KEGG

module	
0	**Immune response**
1	**Carbon metab. in cancer**
2	**mRNA metabolism**

3	**Integrin signaling**
4	**Transcription**
5	**Translation**
6	**DNA damage control**
7	**RNA degradation**
8	**Lipid metabolism**
9	**Mitosis**
10	**Hedgehog signaling/ addiction**
11	**rRNA processing**
	Tight junction / Protein

12 folding

t for all enhancer target genes, their host genes and promoter genes (FDR <0.01)

pathway
JAK-STAT signaling pathway(K)
Pathways in cancer(K)
CD40/CD40L signaling(N)
NF-kappa B signaling pathway(K)
Th17 cell differentiation(K)
Cytokine-cytokine receptor interaction(K)
tnfr2 signaling pathway(B)
IL12-mediated signaling events(N)
Inflammatory bowel disease(K)
Adipocytokine signaling pathway(K)
RIG-I-like receptor signaling pathway(K)
Viral carcinogenesis(K)
DDX58/IFIH1-mediated induction of interferon-alpha/beta(R)
the 41bb-dependent immune response(B)
Longevity regulating pathway(K)
Small cell lung cancer(K)
IL-17 signaling pathway(K)
Hematopoietic cell lineage(K)
TNF signaling pathway(K)
AMPK signaling pathway(K)
hiv-1 nef: negative effector of fas and tnf(B)
Measles(K)
Autophagy - other(K)
HIV-1 Nef: Negative effector of Fas and TNF-alpha(N)
PI3K-Akt signaling pathway(K)
IL2 signaling events mediated by PI3K(N)
Hepatitis C(K)
IL23-mediated signaling events(N)
Hepatitis B(K)
Influenza A(K)
MTOR signalling(R)
LKB1 signaling events(N)
TNF receptor signaling pathway(N)
keratinocyte differentiation(B)
Central carbon metabolism in cancer(K)
Processing of Capped Intron-Containing Pre-mRNA(R)
Spliceosome(K)
Beta2 integrin cell surface interactions(N)
Integrin signalling pathway(P)
Immunoregulatory interactions between a Lymphoid and a non-Lymphoid cell(R)
Viral myocarditis(K)
Extracellular matrix organization(R)

Leukocyte transendothelial migration(K)
SNARE interactions in vesicular transport(K)
Malaria(K)

RNA Polymerase II Transcription(R)
Signaling events mediated by HDAC Class I(N)
Factors involved in megakaryocyte development and platelet production(R)

SRP-dependent cotranslational protein targeting to membrane(R)
Response of EIF2AK4 (GCN2) to amino acid deficiency(R)
Selenoamino acid metabolism(R)
Eukaryotic Translation Termination(R)
Eukaryotic Translation Elongation(R)
Nonsense-Mediated Decay (NMD)(R)
Eukaryotic Translation Initiation(R)
Insertion of tail-anchored proteins into the endoplasmic reticulum membrane(R)
Ribosome(K)
rRNA processing(R)
Signaling by ROBO receptors(R)
Coronavirus disease - COVID-19(K)
Protein processing in endoplasmic reticulum(K)

HDR through Homologous Recombination (HRR) or Single Strand Annealing (SSA)(R)
Nonhomologous End-Joining (NHEJ)(R)
Fanconi Anemia Pathway(R)
DNA Double Strand Break Response(R)
Fanconi anemia pathway(K)
DNA Damage/Telomere Stress Induced Senescence(R)
ATM pathway(N)
Homologous recombination(K)
Fanconi anemia pathway(N)
Cell Cycle Checkpoints(R)

Deadenylation-dependent mRNA decay(R)
RNA degradation(K)
RNA transport(K)
mRNA surveillance pathway(K)
Eukaryotic Translation Initiation(R)

Regulation of lipid metabolism by PPARalpha(R)
Transcriptional regulation of white adipocyte differentiation(R)
RNA Polymerase II Transcription(R)
Signaling events mediated by HDAC Class II(N)
Signaling by NOTCH1(R)
Mitochondrial biogenesis(R)
Cytoprotection by HMOX1(R)

Mitotic G2-G2/M phases(R)
Mitotic Prometaphase(R)
Cilium Assembly(R)

Cocaine addiction(K)
Hedgehog signaling pathway(K)
Amphetamine addiction(K)

rRNA processing(R)
Ribosome biogenesis in eukaryotes(K)

Protein folding(R)

Tight junction(K)
